ON February 19, Dr. Alfred Harker, emeritus reader in petrology in the University of Cambridge, attains his eightieth birthday, and petrologists throughout the world will join in offering their congratulations. Graduating from St. John's College in mathematics in 1882, he had already come into contact with Prof. McKenny Hughes, and was shortly appointed to the staff of the Woodwardian Museum. His earliest original work dealt with the development of cleavage in slates; but he soon turned to petrographic work on the igneous rocks of North Wales, with a series of publications culminating in the Sedgwick prize essay on "The Bala Volcanic Series". In the Lake District, he began (with J. E. Marr) a study of the Shap granite and its aureole, and later of Carrock Fell. During this period also appeared the first edition of "Petrology for Students", now in its seventh edition. From 1895, Harker was for ten years attached to the Scottish branch of the Geological Survey of Great Britain, and worked in Skye and the Small Islands of Inverness-shire, collaborating in the production of the official maps and memoirs, and writing a special memoir on "The Tertiary Igneous Rocks of Skye". Much of this work was necessarily descriptive, and the genetic considerations to which it gave rise were brought together in "The Natural History of Igneous Rocks", a pioneer work on petrology in its treatment of rock-magmas as complex solutions. As president of the Geological Society, he expanded further in his address in 1917 the significance of igneous activity as an integral part of the historical geology of Britain. The central themes of his address the following year, that metamorphism is to be conceived as a progressive change, and that Great Britain offers unique opportunities to investigate such changes, find fuller expression in his book, "Metamorphism", published in 1932. Since his retirement, Dr. Harker has remained actively associated with the petrological collections at Cambridge, where the Harker collection of rock-slides now numbers forty thousand sections. He was awarded the Wollaston Medal of the Geological Society of London in 1922 and a Royal Medal of the Royal Society in 1935.

Prof. František Nušl

IN honour of Prof. F. Nušl, director of the National Observatory of Prague and professor in the Charles University, who has entered on his seventieth year, a composite work has been compiled with the title "Práce věnované Dr. Františku Nušlovi". Prof. Nušl's interest in astronomy is well known; he was vice-president of the International Astronomical Union for the Leyden meeting held in 1928. His circum-zenithal instrument for the determination of time was described before the Czech Academy in Prague (see NATURE, 68, 376; 1903) and also in a number

of other papers. Twelve authors have contributed to the volume and their papers embrace a wide range of subjects. Z. Kopal discusses the two-bodies problem where the central body is an oblate spheroid, not homogeneous, and shows that a steady advance of periastron will take place. V. Guth develops a graphical method for determining the heights and paths of meteors, and J. Štěpánek has a most interesting paper showing the results of photographing Comet Finlay (1937 f) from July 18 until August 15, 1937. It is easy to follow the developments of various parts of the head and tail of the comet by examining these photographs, and also the variations of the different luminous rays. J. Procházka explains his method for investigating the stability of the Bouty meridional telescope at Paris by means of two auxiliary telescopes provided with micrometers, and has found that the stability of the instrument is excellent. J. Svoboda supplies a detailed account of his experimental method for finding the personal error in observations with the Nušl-Friš circum-zenithal instrument. Z. Horák deals with Svoboda's method for determining the radiant of a meteor stream with a minimum of error, and towards the end of his paper shows how very satisfactory results can be obtained by a graphical method. These as well as the other papers, with all of which it is impossible to deal in the limited space, form most interesting reading.

Centenary of the Cell Theory

THE centenary of the cell theory is marked by an article from the pen of Prof. William Seifriz, professor of botany in the University of Pennsylvania, in the recent issue of *Chronica Botanica* (4, No. 6, December 1938). The original theory as propounded by Schleiden and Schwann was faulty; but the immediate theory was, like many other theories, of far less value than the truths which it has been instrumental in ultimately bringing to light. The authors advanced the theory that all organisms are aggregations of structural units or cells; but in his cautiously worded article Prof. Seifriz warns biologists that disciples of the theory tend to attach far more meaning to this than perhaps even its originators intended. The theory established a universal principle of development in living matter; to follow the principle slavishly, in the light of modern knowledge, is wrong; but there is, according to Prof. Seifriz, a tendency to do so. Many biologists seem averse to remoulding their speculations with the advancement of knowledge. Another weakness in the theory is that the cell is viewed as an elementary individual with an autonomy all its own. But this conception is very limited, since the cell is invariably influenced by its environment, such as solutions, temperature, and even the proximity of other cells. That is, the cell is far more plastic than the cell theory would

allow. As Prof. Seifriz emphasizes: "The laws of science as formulated by man are to be commended, even the worst of them, because of the influence they have on further speculation, but they are at best but speculations. . . . In this light must we view the cell theory. Flexibility in thinking comes through mellowness in character and greater willingness to view matters philosophically."

In a less critical, though historically more detailed, article, in the recent issue of *Current Science* (7, No. 6, December 1938), Mr. E. W. Melseon, of the Bausch and Lomb Optical Co., Rochester, New York, claims that the cell theory has been followed by such a wealth of confirmation that we are justified to-day in rating it as the most fundamental concept in the whole science of modern biology. He gives interesting facts concerning the aberrations on cells made by Hooke, Swammerdam, Malpighi, Van Leeuwenhoek and Wolff. They, together with others mentioned, collected much data concerning cells. They undoubtedly saw them and probably their nuclei; but the significance escaped them. Dutrochet published in the eighteen twenties much material which showed his clear conception of the anatomical identity of the cell. In fact, it seems that it was Dutrochet's experiments on physiology which made the recognition of the cell as a structural, functional and developmental unit a necessity. But the nucleus was left out. Schleiden's greatest contribution rests on his recognition that increase in the size and number of cells is responsible for growth, and Schwann's his statement that "The elementary parts of all tissues are formed of cells in an analogous, though very diversified manner, so that it may be asserted that there is one universal principle of development for the elementary parts of organisms, however different, and that this principle is the formation of cells. . . ." But we feel, with Prof. Seifriz, that biologists tend to be incautious of the theory, especially in elementary biological teaching, and do not realize sufficiently that neither Schleiden nor Schwann had at their disposal present-day knowledge of nuclear structure, mitotic division and all the modern concepts in genetics and cytology.

Evidential Value of Blood Groups in Litigation

THE debate on the second reading of the Bastardy (Blood Tests) Bill, introduced by Lord Merthyr, which took place in the House of Lords on February 8, was no less noteworthy for the tribute paid by Viscount Dawson of Penn to the work of Mendel in the study of inheritance than for the cogency of the arguments with which his Lordship supported the objects of the legislation proposed. Clause 1 of the Bill states that in applications for affiliation orders a court may, and at the request of either party shall, order a test to be made of the blood of all three parties in the case. Lord Dawson's insistence on the urgent desirability of substituting objective evidence for the human and subjective in this class of legal action, which is peculiarly open to the danger of a miscarriage of justice—a contention in which he was followed with characteristic vigour

by Lord Raglan—will be welcomed by all who concur in the view that the scientifically attested fact is the surest guide to right judgment. At the same time his recapitulation of the scientific evidence, on which confidence in the blood group test is based, will both inform public opinion as to its potentialities, while removing certain popular misconceptions as to its scope by the emphasis laid on its limitations. It was pointed out by both Lord Merthyr and Lord Dawson that the blood test provides no more than negative evidence, that is evidence of non-paternity, to the extent, it is estimated, of 30 per cent of innocent men. In the course of the debate it was pointed out that the application of the test in this connexion had been widely adopted in other countries and its supporters "were culled not from the scientists of one country, but from the whole civilized world". "It was," it was said further, "a slur on the medicine and law of this country that we were so long in adopting something so completely proved". The Bill was referred for inquiry to a Select Committee of the House; but the Lord Chancellor in summing up the arguments, mostly of a practical nature, against adoption of the Bill, accepted Lord Dawson's scientific view as "completely reliable".

New Explanation of the Great Glen Fault

THE powerful dislocation which intersects Scotland in a north-east and south-west direction along the line of the Great Glen has usually been interpreted by geologists as a normal fault with a vertical downthrow on its south-eastern side. In an important paper read before the Geological Society of London on February 8, however, Dr. W. Q. Kennedy brought forward new evidence which leads him to believe the fracture as a strike-slip or wrench fault with a true lateral displacement of approximately 65 miles. It belongs, therefore, to the same class as the San Andreas rift of California and, like the latter, presumably extends downward at least to the base of the earth's granitic shell. This conclusion is supported by several independent lines of evidence. (a) The Great Glen fault belongs to the same system as the Strathconan, Ericht-Laidon and Loch Tay faults, all of which have proved lateral displacements of up to five miles. (b) It possesses characters unlike those of a normal fault but similar to other strike-slip dislocations (for example, singularly smooth, straight outcrop and abnormally wide shatter-belt). (c) It displaces the great north-south injection belt of the Moine Series for a distance of at least sixty miles. (d) It truncates the Strontian granite, the southern portion of which, according to the detailed structural evidence, is missing. The missing half, however, has now been identified in the Foyers granite, which outcrops on the other side of the fault some sixty-five miles to the north-east and is similarly truncated by the fracture. These two intrusions consist of identical rock-types and agree in all details of internal and external structure. This interpretation clarifies certain obscure features of Scottish geology and serves to explain the southern continuation of the Moine Thrust in Islay. The fault is still active but the main lateral movement appears to have been

accomplished in Upper Devonian or Lower Old Red Sandstone times. The dynamical interpretation of the movement, moreover, indicates that the fault must have resulted from a regional compression which acted in a north and south direction. The fracture is, therefore, unrelated to any Caledonian pressure or tension, but formed as a result of early Hercynian pressure.

British Industries Fair

THE British Industries Fair, 1939, will open on February 20. It is divided into two main sections—one at London and the other at Birmingham; and the London section is again divided into two groups—one at Olympia and the other at Earl's Court. The number of overseas buyers who have intimated their intention to come to the Fair is six hundred more than last year and they are coming from no fewer than 66 countries. Holland heads the list, sending 607 compared with 465 last year. Belgium is second, 293 having accepted as against 245. Eire is sending 269 as against 207; Poland, 164 compared with 72; Czechoslovakia, despite recent happenings, 154 as against 37; Hungary, 110 as against 19; from Denmark there is a slight falling off, 105 compared with 112; and from Switzerland 98 are coming, as against 79 last year. The hardware and heavy industries section of the Fair will be held, as heretofore, at Castle Bromwich, Birmingham. At Earl's Court the main exhibits will be those of the textile and furnishing trades, and also an Empire section. At Olympia the trades exhibited will include chemicals (light and heavy), scientific instruments, photographic and cinematographic apparatus, radio apparatus and plastics, in addition to a large number of other industries, such as glass and leather, usually regarded as belonging to the category of light industries. Among the chemical exhibits, that of Imperial Chemical Industries, Ltd., repeats the practice, introduced by this firm last year, of showing only one major product at a time. Last year the subject was soda; this year it will be ammonia. Exhibits will be shown in six main groups: the use of ammonia in its anhydrous form; as ammonia liquor; as ammonium compounds; oxidised to nitric acid; converted to cyanide; and converted to urea.

As in recent years, the scientific instruments section will form a prominent and notable part of the exhibits at Olympia. The national rearmament programme has naturally involved the production on an enormous scale of the scientific instruments needed for the control of the various major weapons of war—such as range finders, periscopes, gun sights, bomb sights and cameras. The latest type of anti-aircraft searchlight will be shown in action, and forms a central feature of the composite stand of this section. It is perhaps not generally realised that the speeds of modern aircraft are such that the anti-aircraft gun may have to be directed as much as two miles ahead to enable the projectile to hit the target. 'Predictors', which automatically calculate this position, are now in general use by anti-aircraft batteries. The War Office has given permission for

an anti-aircraft predictor to be displayed and a staff sergeant will be in attendance to give the public information. A photographic apparatus will be shown, which enables a photographic record to be made of a 500-page book on only 30 ft. of film—an apparatus obviously of great potential use to libraries. Among other apparatus and instruments to be exhibited will be the latest cinematographic projector; a new type of highly efficient loudspeaker of very small dimensions; a projection saccharimeter, which gives an image on the screen showing the percentage of sugar in various foods; and a recent form of dust counter—the 'thermal precipitator'.

Methods in the Study of Man

NUMEROUS questions of general interest, but in their immediate bearing more nearly affecting those concerned with teaching and research in the study of man, were raised by Dr. Henry Balfour in his Fraser Lecture delivered at Liverpool in 1937 and recently issued in pamphlet form (*"Spinners and Weavers in Anthropological Research"*. Oxford: at the Clarendon Press, 1938. Pp. 19). The science of anthropology is a relatively young science; but its progress in recent years has been remarkably rapid. This has been due largely to a vigorous growth of specialisation. So much so, indeed, that not only has it brought about a condition which now renders it unwieldy for the individual, but as Dr. Balfour pointed out, there is a real danger that the major problem, the full comprehension of man's nature and potentialities, may be lost sight of, through increasing individual enthusiasm over one or other branch of the general science of 'anthropology'. Dr. Balfour himself was convinced not merely that there is place for both the 'generalist' and the 'specialist', but in fact that there is a real need for their co-operation as a condition of orderly advance in the future development of the science. Metaphorically their relation is expressed in the title of Dr. Balfour's lecture. Taking as an example the methods employed in one of the departments of his own special branch of study, technology, he expounds how in his conception of the relation of the diverse methods of study, the 'spinner', the specialist, provides the threads of surely grounded data from which the weaver, the 'generalist', fashions the fabric of theory. Among the conclusions which follow from this conception to which Dr. Balfour referred, not the least significant is that which develops its bearing on the organisation of the curriculum for the anthropological student.

Archaeological Interpretation and Modern Analogies

Among other matters upon which Dr. Balfour touched as incidental to the main thesis of his Fraser Lecture, not the least interesting is the interpretation of archaeological data in the light of reference to objects of the material culture and to the practices and beliefs of modern and still-surviving peoples of backward culture. He recalled the opportunity for such a comparison, which was lost irretrievably when the Tasmanians, a people still living the life of paleolithic man, were allowed to die out in the last century and themselves became the subjects of the archaeo-

logical method of research. Although it is widely appreciated that in the archaeological studies of the last generation nothing has contributed more fruitfully to understanding of the culture of the stone age than the interpretation of the palaeolithic cave paintings of southern France and Spain by reference to the magical and religious beliefs of modern 'savages', nevertheless many archaeologists hesitate to press such analogies. They point to the unquestionable fact that the culture of the modern 'primitive' has not been static over a long period, but has itself been the subject of an evolutionary process, even though they may admit with Dr. Balfour that change has been slow, when no extraneous element has been implicated. Yet instances of the prolonged persistence of unchanged tradition do undoubtedly occur. An interesting illustration bearing on the argument is afforded by Mr. S. Casson's study in *Antiquity* of December last of survivals among ceramic types now current in Cyprus and the islands of the Aegean, belonging to a tradition which extends back not only to medieval times, but even in some instances to the bronze age. He points out how the methods of manufacture, marketing and distribution between the islands and to the mainland still followed at the present day may serve, with their Homeric flavour, to throw light on the obscure field of the early industrial and commercial organization of the eastern Mediterranean, about which so little is known in detail.

Research in Mental Disease at Birmingham

ON February 9, a memorial plaque to the memory of the late Sir Frederick Mott was unveiled by Lady Mott in the Medical School of the University of Birmingham at Edgbaston. The plaque, which is the work of Miss Phyllis Mott, the daughter of Sir Frederick, was the gift of Dr. H. A. Pullar Strecker. Sir Gilbert Barling, in an introductory address, said that the Joint Board for Research in Mental Disease has now found its home in the new Medical School of the University, where it has excellent laboratory accommodation. The laboratory was originally opened at Hollymoor in 1923 by the Minister of Health (the present Prime Minister) with Sir Frederick Mott as honorary director of the Joint Board of Research, and Dr. F. A. Pickworth as chief research officer. It was hoped that the mental hospitals in the surrounding counties would join in the research, and this hope is now fulfilled by Staffordshire, Leicestershire, Worcestershire and Shropshire. Sir Gilbert acknowledged the generous help of Sir Charles Hyde both in 1923 and at the present time. Funds are now available for the appointment of another full-time research officer of high standing to study the influence of viruses and hormones as causes of mental disease, and a surplus is to be used to provide the stipend of a research scholar for three or four years.

Roman Road near East Grinstead

A ROMAN road, which is described as "one of the most perfectly preserved of its type in Britain", has been discovered in a field at Holtys near East Grinstead (*The Times*, February 13). It is part of the

old Roman highway which ran from London to Lewes and here crosses a field. The land on which it is situated has been purchased by Mr. I. D. Margary, a Sussex archaeologist, for the purpose of investigation and later preservation. At present a stretch of the road, about 85 yards long and varying in width from 15 to 18 ft., has been uncovered. Wheel marks are plainly visible; but the iron-lag surface has rusted together so solidly as to form a mass almost as hard as concrete, and consequently in an excellent state of preservation. In certain places it has been necessary for the workmen to remove soil to a depth of three feet to reach the surface of the road. The remains of vegetation several inches in depth indicate that at one time a forest grew over the road.

Research in Electrical Industries

LORD STAMP, the new president of the British Electrical and Allied Industries Research Association, when addressing members at a luncheon which followed the annual meeting in London on February 10, laid stress on the value of research in industry. He pointed out that the electrical industry takes a leading place in research because it has no real industrial or commercial history apart from the history of research and invention. Most industries grow out of, and often cling to, primitive operations on raw materials to supply age-old needs. Scientific research, if added to them, complicates them; and many think that these additions are a doubtful advantage if they cannot be confined to benefit those who promote them. They think that it makes competition more keen in various branches of the industry and often, as well, creates unnecessarily rapid obsolescence in plants still working. The whole genesis of the electrical industry has been different; it was born out of research and is meeting the created needs of an advanced civilisation. Continuous research is its natural sustenance. The work of this Association is an excellent example of co-operation between manufacturers and users; it pools their ideas, thus ensuring that both sides get full benefit from them.

Thermal Power Plants for Emergency Service

A MAJOR interruption of the electric supply in a city of any importance is nowadays attended with disastrous consequences. The provision of some reserve source of power, capable of supplying the vital services at least, is therefore imperative when such failures can occur. The main causes of failures are breakdowns of transmission lines, strikes or enemy bombardment. A paper read by Mr. Hvistendahl on November 10 to the Institution of Electrical Engineers distinguishes between the different classes of service to be furnished by stand-by plants. Descriptions are given of automatic and semi-automatic stand-by plants used in towns in Norway and Sweden. Although unthinkable a few years ago, the bomb-proof emergency service station is now a grim reality. Sandbags provide some protection against fragments of stray shells or bombs, but they are little use against repeated attacks from the air,

and a large steam-power station is an easily located target. This has led to the construction in several countries of the Continent of bomb-proof stand-by power plants for the essential services in towns or districts or for supplying the power requirements of munition factories. These plants are either of the surface or of the underground type. The plan of a station for an output of 10,000 kw. is shown located in a tunnel cut into the face of a cliff. The turbo-set, boiler and tanks containing sufficient fuel for 7-10 days' service, and the auxiliary starting set, are accommodated in a gallery about 150 ft. long and of about the section of a normal double-track railway tunnel. When ground conditions are not favourable to such a disposition, or the danger of flooding exists, a station of the surface type is adopted, with roof and walls of reinforced concrete about 4 ft. thick, having the appearance of a block of dwelling houses or made inconspicuous in some other way.

A Naturalists' Directory

WE have recently received a copy of the thirty-first edition of the 'Naturalists' Diary' (Salem, Mass., U.S.A.: The Cassino Press. 3 dollars). It contains the names, addresses and special subjects of professional and amateur naturalists of North and South America, etc. This list will prove very useful to naturalists in the United States, since for that country it seems comprehensive; but in other countries, such as Great Britain, its usefulness is impaired by the sparsity of entries. For example, for the State of New York alone there are about four hundred and fifty entries, while for the whole of Great Britain there are only eleven; for France, six and for Germany, six. The list should prove useful, however, to naturalists outside the United States who wish to get in touch with their American contemporaries. Appended to this directory is a short list of scientific periodicals. While in the compilation of such a list it is naturally essential to be selective, it is difficult to understand what policy was adopted by the compilers, since it is rather inconsistent. Most of the periodicals are American; but even here it is difficult to see why the *Journal of Applied Physics* should be included in a list for naturalists, and the *Botanical Gazette* omitted. Again, among the British journals is included the *Journal of the Chemical Society*, but not the *Aquarist and Pondkeeper* or *Discovery*. Of foreign journals, only *Scientia* and *Electica Physica Acta* are mentioned, whereas journals of international appeal to naturalists, such as *Chronica Botanica*, are omitted. The price for a paper-covered book of about 280 pages is high.

Periodicals for Medical and Scientific Libraries

THE selection of periodicals for medical and scientific libraries is discussed by O. C. Barnard, Librarian of the London School of Hygiene and Tropical Medicine, in a paper in the *Library Association Record* of November, 1938. Mr. Barnard gives a comparison of results obtained by Gross and Gross'

method of arranging periodicals in order of importance as indicated by the frequency of bibliographical reference to them, taking the *Journal of the American Chemical Society* for 1927 instead of the 1926 volume as used by Gross and Gross. Although agreement is satisfactory at the top of the scale, there are considerable variations lower down, and Mr. Barnard points out that, besides the inherent limitations of the method, which does not take account of frequency of publication of the periodicals or of the length of their articles, comparison on the basis of one year's references is too narrow to be trustworthy. Results obtained at the London School of Hygiene and Tropical Medicine for a large number of medical periodicals by marking each volume or part on the table before return to the shelves are tabulated and discussed, particularly as a check upon the personal selection of experts. Mr. Barnard directs attention to the infrequent reference to the earlier volumes of even such periodicals as *Annales de l'Institut Pasteur* and *Zeitschrift für Hygiene*, and suggests that the compilation of similar records by all libraries co-operating in the inter-library loans system might permit recommendations on the basis of a comprehensive survey which would effect appreciable savings in postage and also in time and labour by the redistribution of certain periodicals among the participants.

ASLIB Conference Report

THE report of proceedings of the fifteenth Conference of the Association of Special Libraries and Information Bureaux (price 5s.), which has just been issued, contains the text of papers presented at the Conference together with summaries of some of those presented at the joint session with the International Federation for Documentation on the organisation of information services. An additional paper from Mr. G. Lightfoot, secretary, Council for Scientific and Industrial Research, Commonwealth of Australia, on the establishment of an information service by that Council is also included, as well as summaries of certain papers contributed to the joint session on 'tools' for library co-operation and reports received from the National Central Library and the British Society for International Bibliography.

Air Raid Precautions in Hospitals

A BOOKLET containing advice on the structural and other precautions that can be taken against air raid risks in hospitals has been issued jointly by the Ministry of Health and the Department of Health for Scotland to all local authorities controlling hospitals and also to voluntary hospitals (London: H.M. Stationery Office. 3d. net). Hospital authorities are urged to proceed at once with the precautions recommended, the extent to which they do so depending in some degree on the likelihood of air attack in the area. Measures are described for the adaptation of existing buildings, as well as structural features suggested for new buildings. The Government is prepared to contribute to the cost of these measures under certain conditions.

England-Cape Town Flight

MR. ALERX HENSHAW had made a new record for the round flight between Gravesend and Cape Town when he returned to Gravesend at 1.51 p.m. on February 9. The total journey of nearly 12,000 miles was made in 4 days 10 hours 16 minutes, thus improving by 1 day 6 hours 44 minutes on the previous record set up by Mr. A. E. Clouston and Mrs. Kirby Green. The Percival Mew Gull aeroplane showed no serious signs of damage and the 200-h.p. Gipsy Six engine was still in good condition at the end of the flight. The times for the journey out and that for the return flight, namely, both about thirty-nine hours, are also records.

Vienna Academy of Sciences: Prize Awards

THE following awards have recently been made by the Academy of Sciences in Vienna: Haitinger prize for physics to Dr. H. Haberlandt, for his work on the luminescence of fluorites and other minerals; Rudolf Wegscheider prize for chemistry to Dr. R. Kuhn, for his work on lactoflavine; Fritz Pregl prize for microchemistry to Dr. F. Hecht, for his work on microchemical analysis, particularly of thorium, monazite and uranium minerals; Hanseigir prize for astronomy to Dr. M. Beyer, for his work on the photometry of stars, and in particular for his work on variable stars.

Announcements

THE James Scott Prize (1938) of the Royal Society of Edinburgh was presented to Prof. P. A. M. Dirac, at the ordinary meeting of the Society held on February 6, when he delivered an address entitled "The Relation between Mathematics and Physics".

THE James Alfred Ewing Medal of the Institution of Civil Engineers has been awarded to Prof. A. H. Gibson, professor of engineering in the University of Manchester. This Medal was founded in 1936 in memory of the late Sir Alfred Ewing, and is awarded to a person, whether a member of the Institution or not, for specially meritorious contributions to the science of engineering in the field of research.

PROF. F. G. DONNAN has been elected president of the Association of Scientific Workers, in succession to Sir F. Gowland Hopkins, whose term of office has recently ended.

DR. FABRIS GROSS, lecturer in experimental zoology in the University of Edinburgh, has been elected the first holder of the Jacobson fellowship for research in the new Oceanografiska Institutet of Göteborg, Sweden. The research is in connexion with the inauguration of a new plankton-well, in which the life-histories of plankton may be studied in conditions resembling as closely as possible those in the sea. The University has granted Dr. Gross leave of absence to cover the period of the investigation.

PROF. ADOLF WINDAUS has been awarded the Pasteur Medal for his lectures in Paris on the investigation of vitamins.

SIXTEEN more names have been added to the memorial erected by the German Röntgen Society in commemoration of those roentgenologists and radiologists who sacrificed their lives to science.

M. BERNARD LYOT, who has been awarded the Gold Medal for 1939 of the Royal Astronomical Society, will deliver the George Darwin Lecture at the ordinary meeting of the Society on May 12. The lecture will be illustrated by a film showing the motion of matter in solar prominences and by photographs of the solar corona in the absence of a total eclipse.

At a meeting of the Royal Astronomical Society held on February 10, the following officers were elected: *President*, Prof. H. O. Plummer; *Vice-Presidents*, Prof. S. Chapman, Mr. W. M. H. Greaves, Dr. H. Spencer Jones and Prof. F. J. M. Stratton; *Treasurer*, Mr. J. H. Reynolds; *Secretaries*, Prof. H. H. Plaskett and Mr. D. H. Sadler; *Foreign Secretary*, Sir Arthur Eddington.

THE Division for the Social and International Relations of Science of the British Association is holding a meeting at the University of Reading on March 28 to consider "Milk in its Nutritional Aspects". Further information will shortly be obtainable from the Secretary, British Association, Burlington House, Piccadilly, London, W.1.

THE annual general meeting of the Association of Technical Institutions will be held in London on February 24-25. Three discussions will be held, namely, (1) on the Report of the Consultative Committee; (2) on the Report on Libraries in Technical Institutions; (3) on the Report on Psychological Tests. Further information can be obtained from Dr. H. Schofield, Loughborough College, Loughborough, Leicestershire.

THE Minister of Health has approved an order made by Slough Town Council under the Town and Country Planning Act, 1932, for the preservation of Observatory House, Slough, the residence of Sir William Herschel, where he set up his famous 40-ft. telescope, and also of his son, Sir John Herschel.

THE fifth Elihu Root Lecture entitled "Cultural Contacts of Science" delivered by Sir Richard Gregory on December 8, in the Elihu Root Hall of the Carnegie Institution of Washington, extracts from which were printed in *NATURE* of December 19 p. 1059, has now been issued in book form. The Elihu Root Lectures were founded to deal with the influence of science and research on current thought. Copies may be obtained from the Carnegie Institution of Washington, Washington, D.C.

It was stated in the report received from the British Museum (Natural History) that the diamond presented by Sir Ernest Oppenheimer to the Museum was the first to be taken from the Kimberley diamond mines (*NATURE*, Feb. 4, p. 195). We are informed that this is incorrect. The stone came from the Jagersfontein mine in the Orange Free State.

Research Items

Organization of Labour in Ancient Egypt

It is remarkable that so few records of times taken for ancient enterprise, excepting wars, have been preserved. From one such record, the construction by King Amenophis III of a vast lake of which the site is considered to be a rectangular enclosure near the temple at Medinet Habu, Mr. R. Engelbach and Mr. J. W. Macaldin have endeavoured to arrive at an estimate of the number of workmen employed to have produced this work within the period named (*Bull. de l'Inst. d'Égypte*, 20; 1938). The rectangular enclosure is in size some 2200 metres by 1000 metres. On four commemorative scarabs known, of which one is only a fragment, it is stated that on the sixteenth day the king and his consort sailed on the lake in the royal barge; but it is pointed out by Breasted that the dimensions of the lake differ from those given on the scarabs. Air photographs, however, suggest that although the length-breadth proportions are different, the variant dimensions can be reconciled. Though the lake is generally described as a pleasure lake for Queen Tyi, this is not mentioned on the scarabs; and it is probable that it was intended to serve as a harbour for the numerous boats which would be required by the new palace built by Amenophis. The possibility whether the lake could have been constructed in the time depends upon the number of diggers who could be put to work simultaneously in the space and efficiently served by carriers of the spoil. The only method feasible would be to divide the area into a number of bays, in each of which it is calculated 184 diggers could work while leaving space for the passage of the carriers. This method of excavating is followed in modern Egypt, and on this basis it is calculated that 184 diggers could excavate a bay in 13.96 days. Taking the distance to the still existing mounds of spoil, the calculation gives 50,968 diggers, 50,968 diggers' mates and 675,826 carriers; total, 777,262 men. If, however, the carrying were reduced to temporarily dumping the soil by the side of the lake for later transport to a greater distance, the carriers might be reduced to 140,716.

North American Birds of Prey

THE most complete account of the life-histories of the birds of any country is that now being published by the U.S. National Museum in its series of *Bulletins*. The series began in 1919 and now with Part 2 of the birds of prey has reached its eleventh volume (*Bulletin*, 170; 1938). This part is as thorough as its predecessors, giving as full an account as possible of the life-history of the best-known species of each species, and

as Outram Bangs showed in 1930, has a considerable range in the States. The author, Arthur Cleveland Bent, finally, one hopes, gives the lie to the old fable of the communal life of the burrowing owl with the prairie dogs and rattle-snakes of the western plains. He points out that so comprehensive a work can only be the result of co-operation, and that if any reader fails to find in the volumes anything that he knows about birds, he can blame himself for not having sent in the information. Thus is the critic disarmed.

Nicotine and Bees

In the *Bee World* of January 1939, a short but interesting account is given of the work of F. K. Böttcher, published in *Die Gartenbauwissenschaft* (12, 2; 1938) on the effect of nicotine on bees. It appears that this substance repels bees, and that it is difficult to induce them to take it. When nicotine was added to the drinking water of the bees at any strength over 0.05 per cent, it repelled these insects so much that there was no fear of their imbibing much of it. When a field of mustard was dusted with nicotine in the usual way (2.5 per cent) most forager bees were driven away; only a few became poisoned. Neither dusting nor spraying caused any damage of practical importance to the colonies. It can be concluded, therefore, that when nicotine is used as a dust or as a spray in concentrations of 0.15-2.5 per cent, no damage of practical importance to bees results. This work, if confirmed, is important to bee-keepers and fruit-growers in view of the repeated warnings given about the damage caused by nicotine applications to fruit trees when the blossoms are visited by bees.

Induced Polyploidy by Treatment with Colchicine

A REPORT was presented by A. J. T. Mendes, of the Instituto Agronomico do E. de S. Paulo Campinas, Brazil, at the first South American Botanical Meeting held at Rio de Janeiro, last October, on the preliminary results obtained by treatment of seed and plants of coffee, cotton and tobacco with colchicine. The embryo of the coffee seed is surrounded by a large amount of nutritive matter; the seedlings are grown in solutions as strong as 0.6 per cent. After 35 days did not produce chlorophyll, and no germination. But a 0.1 per cent solution after during 4 days was better. The seedlings were

Pollen Tubes of Cotton

A STUDY of various problems connected with the growth of pollen tubes in cotton has been made by N. K. Iyengar (*J. Genetics*, 37, No. 1). The method found most satisfactory was by direct observation of the pollen tubes in the pistil after suitable treatment. There is a central conducting tissue in the style, and the tubes run for some distance over the placenta before reaching a micropyle. The pollen grains germinate promptly on the stigma, putting forth several tubes which form some branches in the style. Callose plugs are also described. The tetraploid cottons generally have larger pollen grains and wider pollen tubes than the diploids. When the two are present on the same stigma they both germinate, but the self pollen takes part in fertilization. Two to four pollen tubes sometimes enter one micropyle; but there is no evidence that more than one takes part in fertilization. By examining the ovary 25½ hours after pollination, evidence was obtained regarding the order of entry of the pollen tubes into different ovules of the flower. It was found that the first ovules in a locule to receive pollen need not necessarily be the ones nearest the stigma.

Synthesis of Polyploid Types by Hybridization

MÜNTZING's experiments on hybrid incompatibility and the origin of polyploids has brought out the fact that zygotes tend to be more viable if produced by union of gametes with approximately the same chromosome number. M. Skalińska (*Bull. Int. de l'Acad. Polonaise des Sci. et Lett., B, Sci. Nat.* (1) 1938) in carrying out breeding experiments with hyperdiploid *Aquilegia* plants with 15 ($2n + 1$) and 16 ($2n + 2$) chromosomes, obtained a proportion of giant pollen grains by formation at meiosis of restitution nuclei, fusion of spindles in meiosis II or unipolar spindle fusion, giving diploid and extra chromosome types of pollen. It was concluded that such giant grains would compete favourably with haploid or hyperhaploid grains in tetraploid tissues. The results of such crosses fully confirmed Müntzing's observations as pollination of the tetraploid with pollen containing a proportion of giant grains produced, in addition to one triploid ($21 = 3n$) and one hypertriploid ($23 = 3n + 2$), tetraploid (28) and hyper-tetraploid plants with 29 ($4n + 1$) and 30 ($4n + 2$)

no correlation between their shock-frequency curves; but if we assume a hypothetical endogenous cause for all these regional tectonic movements, then this cause must be the connecting link between them and hence between the several earthquake shocks.

Heats of Combustion of Diamond and Graphite, etc.

Three recent papers (*J. Res. Nat. Bur. Stand.*, 21, 457, 475, 491; 1938) by P. H. Dewey, D. R. Harper, R. S. Jessup and F. D. Rossini deal with anthracite cookes, natural and artificial graphites and diamonds from the point of view of heats of combustion and stability, and provide important new data in this interesting field of thermochemistry. In agreement with previous results, it is found that the heat of combustion of 'amorphous' carbon is higher than that of diamond, and that of diamond is higher than that of graphite. The results are expressed in international kilojoules per mol (12.01 gm.) of carbon to form CO, at 25° and 1 atm. pressure without the production of external work. The results do not indicate the existence of different forms of graphite and diamond. The values are: graphite, 393.388 int. k.j. (94,080 gm. cal.); diamond, 395.287 int. k.j. (94,484 gm. cal.); 'amorphous' carbon, 403.03 int. k.j. (extrapolated to zero hydrogen content). The papers contain thermodynamic discussions of the stability of the forms of carbon and deal critically with a large amount of numerical data.

Accuracy of Meteor Data

In a previous paper (*J. Brit. Astro. Assoc.*, 48, 9; July 1938), J. G. Porter discussed the errors in the true paths of doubly observed meteors, and in a recent paper (*J. Brit. Astro. Assoc.*, 49, 3; Jan. 1939) he deals with the accuracy of radiants. Porter utilized thirty-five doubly observed Perseids from 1934 until 1937, and his procedure consisted in determining the true radiant from the elements of Comet 1862 iii which is responsible for the Perseid shower. As the Perseids persist for an unusually long time, computations of radiants were made from July 29 until August 16, and these were compared with the radiants deduced from doubly observed meteors. A very full analysis of the results is made, and, although only thirty-five doubly observed meteors were available, it is highly probable that the deductions are a safe criterion regarding observational errors in general, or at least for the British observers. The probable error of the radiants is $\pm 2.4^\circ$, and this is very small compared with the results found for American observers. Opik accepted a probable error of $\pm 8^\circ$ for the Arizona Meteor Expedition observers, and others have quoted even higher figures. Various other deductions were made from the analysis in this and the previous paper, amongst which the following may be noticed: For the deviations of the flight-paths the probable error was $\pm 2.54^\circ$, and errors of the same order were found in the mean *zenithal* deviation of apparent to *zenithal* by a simple formula suggested

Earthquake Shocks

of the earthquakes with ... in the Philippine ... is of the opinion ... in-

addresses stressing the importance of the meeting. Prof. Gorneth then introduced and explained the subject to be discussed.

At the meetings the following six papers were discussed: "The Significance of the Skolem-Löwenheim Theorem" (Prof. Th. Skolem); "General Analysis of the Question of Fundamentals" (Prof. M. Fréchet); "Logic and the Question of Fundamentals" (Prof. J. Łukasiewicz); "Controversies Regarding the Theory of 'Ensembles' and the Question of Fundamentals" (Prof. H. Lebesgue); "The Role of the Axiom of Choice, and the Hypothesis of

Continuity in Mathematics" (Prof. W. Sierpinski); "The Present Position in regard to Hilbertism" (Prof. Bernays).

At the end of the meeting Prof. Gorneth summed up the general conclusions to be drawn from the discussions, and expressed his thanks to the Institute of Intellectual Co-operation for its help and collaboration.

The texts of the various papers submitted and an account of the discussions will appear in the fourth volume of the new Scientific Series being published by the Institute.

Molecular Structure

A DISCUSSION on molecular structure was held by the London Mathematical Society on January 19 in the lecture room of the Royal Astronomical Society, the president, Prof. E. A. Milne, being in the chair. The discussion was opened by Dr. W. G. Penney; Dr. H. A. Jahn, Dr. C. A. Coulson and Mr. G. J. Kynch made further contributions, and Prof. J. E. Lennard-Jones summarized the discussion.

Dr. W. G. Penney (Imperial College, London) said that the nuclei of a polyatomic molecule in its most stable state are practically at rest and that the electrons move about in a highly complicated, but regular, way. If the nuclei are slightly disturbed, they vibrate, and their motion can be described in terms of a number of normal modes. Such vibrations can be detected in the infra-red spectrum.

to calculate W by perturbation methods. Thus, ψ is expanded in terms of the ψ_a , the Schrödinger functions of the separate atoms. Substituting this in (1), leads to

$$[H^1 - W(x_1, x_2 \dots)] \sum a_a \psi_a = 0.$$

Multiplying by the ψ_a in succession, and integrating over the configurational space, leads to a set of equations in the a_a . Eliminating the a_a gives a determinantal equation for $W(x_1, x_2 \dots)$. Minimizing with respect to $x_1, x_2 \dots$ gives the equilibrium configuration and the heat of formation; expanding about the minimal configuration leads to the frequencies of the normal modes.

Detailed considerations of the function $W(x_1, x_2 \dots)$ show, for example, that if four monovalent atoms are combined with a carbon atom, they are distributed

around the carbon atom in the directions of the corners of a regular tetrahedron. If the carbon atom is linked directly to only three atoms, so that one of the bonds is double, the system is co-planar. When the carbon atom is linked to only two atoms, so that both bonds are double, or one is triple and the other single, the system is linear.

Little progress has been made in calculating the energies of formation and the vibration frequencies of molecules in excited states, and the description of their absorption spectra is therefore at present only qualitative. A similar, but simpler, problem is that of interpreting the absorption spectra of rare earth crystals. The spectrum is that of an inner group of electrons of the metal ion, and the energy levels are very near those of the free ion.

Dr. H. A. Jahn (Davy Faraday Laboratory, Royal Institution) discussed the vibrational potential energy constants of polyatomic molecules. He showed how, starting from a given equilibrium configuration of a polyatomic molecule and making use of the invariance of the vibrational potential energy with respect to all the operations of the group of symmetry of the equilibrium configuration, the most general form of the elastic potential can be determined.

Mathematically, the invariance of the vibrational potential energy is equivalent to the fact that the matrix of its coefficients must commute with all those matrices which show how the normal displacements transform under the symmetry operations of

		Potential energy			
		A_1	E	F_1	F_2
Regular tetrahedron.					
Group T_d .	A_1	k_1			
	E		k_1		
Vibrations:			k_2		
$A_1 + E + 2F_1$.	F_1			k_2	k_3
4 frequencies.				k_3	k_3
				k_3	k_3
5 general force constants.	F_2			k_3	k_4
				k_3	k_4

Let $E(x_1, x_2 \dots)$ be the least energy required to separate a molecule into electrons and nuclei, when the nuclei are stationary at $x_1, x_2 \dots$. Then, in principle, $E(x_1, x_2 \dots)$ may be found as the eigen values of the Schrödinger differential equation

$$(H - E) \psi = 0 \quad (1)$$

The energy of formation of the molecule from atoms is

$$W(x_1, x_2 \dots) = E(x_1, x_2 \dots) - \sum E_a$$

where $\sum E_a$ is the sum of the energies of formation of the separate atoms from nuclei and electrons. The equations for the E_a are similar to (1). Since W is very small compared with $\sum E_a$, it is possible

the group. Consequently, by choosing a complete set of vibrational symmetry co-ordinates which transform according to irreducible representations of the group of symmetry, there may be obtained at once, by application of Schur's Lemma, the most general form of the matrix of the potential energy.

This was illustrated by the example of the methane molecule.

Thus, if the methane molecule is a regular tetrahedron, the potential energy has five general force constants and the molecule has four different vibrational frequencies. Similarly, if the molecule has the form of a square pyramid, the group is C_{4v} , the vibrations are $2A_1 + B_1 + 2B_2 + 2E_1$, there are seven different frequencies and ten general force constants. Experimentally four frequencies are found, and the molecule has the form of a regular tetrahedron.

Dr. C. A. Coulson (University College, Dundee) discussed the theory of the carbon-carbon linkages in some simple polyenes and aromatic molecules. Certain hydrocarbons can be adequately described by a single structural formula. Examples are ethane, where the linkage is a single bond, ethylene, where the linkage is a double bond, and acetylene, where the linkage is a triple bond. Other molecules, such as benzene, naphthalene and butadiene, are more complex, and in these cases the linkages must be considered to be of fractional order. General methods of calculating the orders of these linkages have been discovered. They evaluate the energy of a linkage by the approximation of molecular orbitals or of

electron pairs, in terms of a single parameter which measures the difference of energy of the single and double bonds. Linear interpolation then gives the order.

From the experimental values of certain physical constants of the single, double and triple bonds empirical curves may be constructed. These may be used to predict values for the linkages of intermediate order. Thus, the benzene linkage is of order 1.65, and the internuclear distance should be 1.39 Å. in exact agreement with direct observation. Similarly in naphthalene, there should be four types of linkage. Their orders, beginning at the central link and working outwards, are 1.52, 1.56, 1.76, 1.60. The corresponding lengths are 1.42, 1.40, 1.38, 1.40 Å.

Mr. G. J. Kynch (Imperial College, London) discussed the relations between the magnetic properties, specific heat and absorption spectra of rare earth crystals. The deviations of the principal and mean susceptibilities from Curie's law, $\chi/T = \text{constant}$, are caused by an electric crystalline field which perturbs the magnetic ion. Calculations of the magnetic susceptibilities involve the determination of the lowest energy levels of the magnetic ion. These can be compared with those obtained from the measurements of the absorption spectra and the specific heat. Previously, it was thought that a fourth order cubic field would correlate all the data. This no longer seems possible, because of the considerable magnetic anisotropy of the crystals. A new interpretation of the levels found spectroscopically must be sought.

The British Rhætic Flora

PROF. T. M. HARRIS, with experience of the Greenland Rhætic flora behind him, has now studied the British Rhætic beds and, with the application of new methods, described with considerable detail some of the few plants from these rocks (The British Rhætic Flora, British Museum, 1938.) The main outcrop of Rhætic rocks extends from Dorset to north Yorkshire, and it is from these alone that plant remains have been obtained, though smaller outcrops also occur in Wales, Northern Ireland and Scotland. The conception of the Rhætic formation is that of a shallow sea, dotted with islands, and in this, slight changes in level isolated lagoons, which would soon become brackish or freshwater lakes. It is probably in such lakes that the plants grew. The plant-containing beds occur as strata between those containing fish and other marine remains, suggesting temporary incursions of the sea into the lagoon region. The Bristol locality seems to have supplied most of the specimens.

A new method of examination of surface features by reflected light on specimens moistened with paraffin oil has contributed materially to the success of the investigation. The usual methods of rock sections and cellulose nitrate films have also been used; but are difficult with this material.

A common plant is the alga *Botryococcus braunii*, recognizable as colonies, terra-cotta in colour and with characteristic resistance to $\text{HNO}_3 + \text{KClO}_4$. It is probable that this fossil is the same plant which has been described under various names from Ordo-

vician, Carboniferous, Permian, Rhætic, Jurassic and other rocks up to the present day.

Another alga has close resemblance to *Cosmarium*, but owing to failure to recognize sculpturing of the wall, it is provisionally distinguished as *Stenium cosmarioides*.

Perhaps the most interesting plant and one described in amazing detail is *Naiadites lanceolata*, an undoubted bryophyte. Earlier records of Bryophytes are very scanty and only allow the statement that liverworts, probably belonging to the Jungermanniales, extend back to the Carboniferous, whilst records of mosses are more doubtful.

Naiadites is now described with details of stem and leaf form and structure, rhizoids, gemmæ (free and possibly in gemmæ cups, and development of new plantules from gemmæ), archegonia, sporophytes, perianth and spores. The plant is thus sufficiently known to compare with present-day genera. The radial construction and spiral phyllotaxis (3/8) are moss-like features; but the majority of the characters place it in the Hepaticae, and provisionally as nearest to the Riellaceae of the Spharocarpales.

Prof. Harris discusses the conceptions of evolutionary trend in Bryophyta and regards *Naiadites* as supporting rather the view of a reduction series than an up-grade series.

One other plant, *Hepaticites solenotus*, appears to be a hepatic resembling *Anoura*.

Certain other fossils, previously described as Rhætic, seem more correctly to be Liassic.

Training Teachers of Rural Science

IN 1937 the University of Reading Education Department, under the direction of Prof. H. O. Bernard, decided to pay special attention to training teachers for posts in rural senior, central and secondary schools. Three main considerations seemed to make this undertaking a desirable feature of the training course: (1) there was likely to be a considerable and increasing demand for teachers who could teach science with full reference to the rural environment; (2) the University of Reading has a well-organized faculty of agriculture and horticulture; (3) there are in the surrounding countryside several schools which make a speciality of teaching rural subjects.

In instituting the course at Reading, the principle was adopted that it is undesirable to train teachers so narrowly in one aspect of education that they are partially unfitted to see any other aspect. The course in the teaching of rural science was therefore made one of a number of optional subjects, and at present it includes: (a) a series of lectures on general aspects of rural education; (b) occasional lectures by teachers and others actively engaged in rural education; (c) visits to rural schools; (d) teaching practice in rural schools; (e) practical instruction in horticulture and handicrafts.

The lectures deal with such topics as: the meaning of rural education; comparison of rural and urban schools; Hadow and Spens reorganisation in country areas and their implications; the approach to knowledge through practical activities, for example, how the garden can become the centre of a curriculum which differs from the 'normal' only in the principles on which it is devised and the way in which it is developed; the value and the conduct of school expeditions to farms, etc., and the aims, staffing, equipment and finance of gardening, livestock keeping and handicrafts. Special lectures have been given by the head master of a second-

ary school with a strong 'agricultural bias', by one of His Majesty's inspectors of schools who specialises in rural science and by a horticultural organizer to a county council.

Visits to rural schools, when students have been well prepared in what to look for, have proved to be very valuable, and teaching practice in rural schools has been arranged.

Students receive practical instruction in horticulture at the University Horticultural Station. Their work includes preparation of ground, planting, propagation, pruning, crop rotation, managing a small greenhouse or a frame, grafting, etc. In handicrafts, students are encouraged to make apparatus useful for rural activities, such as model greenhouses, cold frames, etc. A short course in metal-work is being developed, in which students may make such things as gate latches, simple agricultural tools, etc.

The course, as at present constituted, is in its infancy, and is in no way static. Some developments which are contemplated are: contact with a senior school within easy distance of the University; a 'model' garden; instruction in livestock keeping; visits to the University farm; and lectures by farmers.

This then is one way in which Reading is trying to help to forge the rather weak link between education and agriculture.

Students of the University of Reading who have graduated in science or agriculture or horticulture, and who have afterwards spent a year in preparation for the education diploma, including the course on teaching rural science, should be well fitted to teach in a rural school of any type. The University Department of Education already conducts, at the request of the Ministry of Agriculture, a fortnight's course in the "Technique of Teaching" for those who hold posts on the agricultural staff of a county authority or similar positions.

Wave-Action and Shore-Lines

AN article by Mr. W. V. Lewis on the "Evolution of Shore-line Curves" (*Proc. Geol. Ass.*, 49, Pt. 2; 1938) is a valuable contribution to a well-worn subject. The author's position is fundamentally that of Sir Henry de la Beche, founder of the Geological Survey, who a hundred years ago stressed the importance both of the longshore drift of material by prevalent waves and the independent action of storm or dominant waves in piling up embankments of detritus in the direction of the greatest force, sometimes at right angles to the shore. In later years opinions changed, and explanation of the evolution of coastal outline was purely on the action of longshore and eddy currents. Latterly, however, there has been a revival of the wave-action hypothesis due largely to the findings of the Royal Commission on Coast Erosion and Afforestation and the work of Steers, Johnson, and others. Mr. Lewis proceeds to examine in detail various sections of coastline in Britain on the Moray Firth, Cardigan Bay, Bristol Channel, Isle of Purbeck and Chesil Bank, and suggests that shore curves, far from being explicable only by reference to longshore currents, yield in certain cases readily to analysis in terms of the direction of

approach of both dominant and prevalent waves, especially the former.

The case of Weymouth Bay and Chesil Bank is of particular interest. It appears that breakwaters in connexion with the Portland Harbour works have caused a modification in the direction of wave approach, with the result that shingle which used to be driven north from Weymouth is now accumulating in front of the town. This means that the bay has swung slightly round so as to face a more easterly direction. As regards the Chesil Bank, it is pointed out that along its sixteen miles from Chesilton to West Bay we have one of the most perfect examples in the British Isles of a shore moulded into line with both dominant and prevalent waves. This gives stability to the curve of the Beach, which exactly faces the direction of open water just clear of Start Point and Ushant into the Atlantic. The grading of the shingle, which increases steadily in size from West Bay to Chesilton, is held to indicate that there is now no permanent drift of material in either direction. In any case the Beach could not have been formed by simple longshore drift, as this would have first filled up the narrow backwater behind.

Science News a Century Ago

Fox Talbot's Photogenic Drawing

At a meeting of the Royal Society on February 21, 1839, further information on photogenic drawing was given in a letter written by Fox Talbot to S. H. Christie, the secretary, dealing with the preparation of the paper and the means of fixing the design. Having chosen a paper of good firm quality, and smooth surface, said Fox Talbot, it was dipped in a weak solution of common salt and wiped dry. One side was then treated with a solution of nitrate of silver. By alternately washing the paper with salt and silver and drying it in between times, the sensitivity of the paper was increased. With regard to the fixing of the images, the author said, that having tried ammonia and several other reagents, the first which gave him a successful result was potassium iodide, much diluted with water. On a photogenic drawing washed over with this liquid an iodide of silver was formed absolutely unalterably by sunshine.

Lighthouses on Sandbanks

In the February 1839 issue of the *Civil Engineer and Architect's Journal*, was an article on the "Construction of Lighthouses on Sands" by the use of the patent screw piles or screw moorings of Alexander Mitchell. On July 4, 1833, Mitchell had secured a patent (No. 6446) for a dock to facilitate the repairing or building of ships, and in this patent he described caissons held in position by means of piles fitted with broad metal screws or worms. Screws could be fitted also to mooring chains. "It having been brought to the notice of the Corporation of the Trinity House," said the *Architect's Journal*, "that the invention might be utilised for establishing lighthouses on sands, they directed an experiment be made by their engineer James Walker. The spot selected for the experiment was the Maplin Sand twenty miles below the Nore, in the mouth of the Thames." Eight screw piles were driven into the sand forming an octagon 40 ft. in diameter, with one in the centre. The piles were wrought iron tubes of 5 in. diameter, 26 ft. long, and each of them was fitted with a screw 4 ft. in diameter. They were driven into the sand 22 ft. by men working on a raft. Afterwards the tops of the piles were braced together to support the lighthouse structure. In 1839-40 a similar lighthouse was built on a submerged sandbank in the entrance to Morecambe Bay.

Earthquake in Leicestershire

THE issue of the *Gentleman's Magazine* for February 1839 contains the following information: "Dec. 23. About four in the afternoon a smart shock of an earthquake was felt at Woodhouse Eaves in Charnwood Forest, Leicestershire. It was preceded by a loud rumbling noise, as of a wagon on the adjoining road, and the shock was sensibly felt by the numerous congregation then assembled in the new church at Woodhouse Eaves; the vibration was so strong as to loosen pieces of mortar from the roof, which several persons heard falling down the slates to the ground. It appears to have been in the direction from the south-west to the north-east or east, from which former point the wind then blew. . . . It is remarkable that an earthquake was felt at Naples about the same time. It is well known to geologists that an antilinal line of strata is in Charnwood Forest."

University Events

BIRMINGHAM.—The pro-chancellor (Mr. Walter Barrow) and the deputy pro-chancellor (Alderman John Henry Lloyd) have recently resigned their posts. Mr. Edmund Phipson Beale is to be nominated as pro-chancellor. Mr. Beale has been on the University Council since 1923 and became treasurer in 1930. He is a son of the first vice-chancellor, Mr. Charles Gabriel Beale, who was appointed when the University was founded. (The title 'vice-chancellor' was, some years ago, replaced by that of 'pro-chancellor', the former having devolved upon the officer originally called 'principal'.) Alderman Lloyd will still remain on the Council as a representative of the City Council.

CAMBRIDGE.—The Jacksonian professorship of natural philosophy became vacant at the end of January on the resignation of Prof. E. V. Appleton, St. John's College, who has been appointed secretary of the Department of Scientific and Industrial Research. It is recommended that candidature at the next election be limited to candidates whose work is connected with atomic physics. It is further proposed that the Jacksonian professor's duties of residence and lecturing shall no longer be specially prescribed.

Prof. P. M. S. Blackett, Langworthy professor of physics in the University of Manchester, has been appointed Scott Lecturer for the year 1939-40.

SHEFFIELD.—Prof. B. H. Bentley, formerly professor of botany in the University, has been appointed emeritus professor.

Dr. S. Haastone has resigned his post of lecturer in physical chemistry.

Societies and Academies

Paris

Academy of Sciences (*O.R.*, 208, 237-312, Jan. 25, 1939).

A. GUILLERMOND and R. GAUTHIER: Effect of pH on the vital staining of yeasts. Absorption of Neutral Red, Cresyl Blue and Nile Blue increases with rising pH; the blue dyes are absorbed by the cytoplasm, the red only in the vacuoles.

A. CHEVALIER: Species, varieties and hybrids of American cotton actually cultivated in tropical Africa, and their improvement.

E. ROUBAUD and R. DESCHENS. Capture of infectious nematode larvae by predatory soil fungi. Active larvae of a species of *Strongyloides* and of a species of *Anoylostoma* were captured and digested (under laboratory conditions) by mycelia of certain soil fungi, suggesting the possibility of biological control of these disease organisms.

W. DOBBLIN: Certain aleatory movements.

A. DEMOULIN: Theory of lines traced on a surface.

G. VAN DER LYN: Analytical representation of abstract polynomials.

J. DUFRÉNOY: Exceptional values of meromorphic functions in the neighbourhood of a given meromorphic function.

V. PLATOFF: Measurement of the reaction of a gaseous jet by the pressure it exerts on a disk.

R. BARTHOLEWYS: New list of stars belonging to the Great Bear stream.

N. CABRERA: Law of multiplication of representative matrices of linear differential operators.

A. PÉREZ and C. VOLLET: Improvements made in definition of the lengths represented by the international standards and in the comparison of these lengths. Certain of the standards have been re-engraved, and the apparatus for comparisons improved.

L. ZACHOVAL: Dispersion of ultra-sonic waves in castor oil.

J. BASSET: Fusion of graphite under very high pressure of argon, up to 4,000 kgm./cm.².

W. UYTENDHOF and C. VERBURG: Temperature of electrons I_e in a positive column discharge with alternating current (50 cycles); results for neon.

O. TE-TCHAO: Formation of large ions in gases as a function of the size of the particles in suspension.

MILM. N. MORGULEFF: Absorption in the visible region of the spectrum by sulphur vapour.

P. LATIN and R. SERVANT: End emission of tubes of luminous gas; part taken by reflections from the walls.

G. COURTOIS: Fusibility of mixtures of pure anhydrous sodium sulphide and carbonate.

M. FOLK: Influence of 'temper' on the density of sodic borate glasses.

J. CURNOT and M. BAUDRAND: Corrosion of welded joints of light alloys.

J. TIMMERMANS, J. DE ROOSTER and J. MICHEL: Spontaneous crystallization and the rate of crystallization of water and of heavy water.

L. S. ORNSTEIN: The theory of liquid crystals.

L. S. ORNSTEIN, J. M. W. MILATZ, E. F. M. VAN DER HELD and W. MAAS: A sensitive method for the measurement of the excitation function of artificial radioactivity.

H. BRINKMAN, L. S. ORNSTEIN and W. LANGENDIJK: Photographic sensitometry for β -ray spectra.

L. S. ORNSTEIN, J. M. W. MILATZ, H. TEN KATE and M. MISSEWICZ: Conditions for the quantitative operation of a Geiger-Müller counter for β -rays. The ionizing power of β -rays as a function of their velocity.

J. G. VAN DER CORPUT and H. J. BACKER: Reaction velocity of mixtures (1). Bimolecular reaction of two mixed substances with a third substance.

L. G. M. BAAS BEKING: Cause of the high acidity in natural waters, especially in brines.

J. F. SCHOUTEN: The perception of subjective tones.

E. F. M. VAN DER HELD: Value of G^2/M^2 in the theory of β -ray spectra.

C. S. MEYER: (1) Integral representations of Whittaker functions. (2) The Kummer function $F_1(a; b; s)$.

M. VAN EIJH: Influence of salt intake on root respiration in *Aster Tripolium*.

F. A. H. W. DE MARRE OYENS: Preliminary note on the occurrence of a new ammonoid fauna of Permian age on the island of Timor.

R. BRUMMEKAMP: Ratio of the surface of the forebrain to that of the whole brain in higher apes and man.

J. L. ADDENS: Presence of a nucleus of Bellonci in reptiles and mammals.

J. DEOOGHEVRE FORTUYN: Systematic arrangement of fibres in capsula interna, thalamus opticus and pes pedunculi.

P. O. FLU: The Mg^{++} cation and lysis of the *Bacterium megatherium* by the antimegathierium bacteriophage.

Washington, D.C.

National Academy of Sciences (Proc., 24, 525-565, Dec. 15, 1938).

H. D. BABCOCK: Some recent observations of sun-spot spectra. Preliminary results with a 21-ft. grating spectrograph with no optical parts except slit and grating, for use in the ultra-violet and photographic infra-red regions.

H. SHAPLEY: Second note on a metagalactic density gradient.

F. G. WATSON: Reflectivity and colour of meteorites. Using a self-recording spectral-photometer, it is concluded, from an examination of seven stony meteorites and one metallic, that they are essentially 'gray-bodies', so that the usual calculation of their temperatures in space are valid. Their geometrical albedoes range from 0.1 to 0.5; colour data do not differentiate between stony and metallic meteors.

W. J. CROZIER and E. WOLF: (1) Duplexity theory of visual response in vertebrates (2). Flicker response of a gecko (rod retina) is little different from that of the diurnal turtle (cone retina), throwing doubt on the validity of associating specifically histological appearance and function in the vertebrate eye. (ii) Specific constants for visual excitation (3). Various animals give the same fundamental form of flicker response curves. They have in common a large assemblage of excitation elements, the frequency distributions of which are fixed by specific genetic constitution.

L. W. LAW: Effects of chemicals on the lethal mutation rate in *Drosophila melanogaster*. Two methods were used: (1) injecting sub-lethal doses into the larvae; (2) immersing fertilized eggs from which the chorion was removed in solutions of sub-lethal concentration of the substances. Copper sulphate increased lethal mutation rate of the X-chromosome. Potassium permanganate and also iodine in potassium iodide produce a slight increase, but colchicine was ineffective.

F. A. BROWN, JUN.: An internal secretion affecting viability in Crustacea. Five species of crayfish (*Cambarus*) were used. Removal of the eyestalk, followed in some cases by injection of eye-stalk tissue into the abdomen, gives results indicating the production in eye-stalk tissue of a chemical substance which is essential to life.

L. M. BLUMENTHAL and G. R. THURMAN: Characterization of pseudo- S_n sets.

B. DE SZ. NAGY: Semi-groups of self-adjoint transformations in Hilbert space.

G. A. MILLER: Groups of order p^m containing $m - \alpha$ independent generators.

Forthcoming Events

[Meetings marked with an asterisk are open to the public.]

Monday, February 20

BEDFORD COLLEGE FOR WOMEN, at 5.15.—Dr. Franz Simon: "The Present Position and Future Objective of Low Temperature Research" (Succeeding lectures on February 22 and 24).*

Tuesday, February 21

UNIVERSITY COLLEGE, LONDON, at 5.15.—G. Tilgham Richards: "The Use of Museums. (3) The Science Museum."*

Thursday, February 23

ROYAL COLLEGE OF PHYSICIANS, at 5.—Dr. Donald Stewart: "Industrial Incapacity and Modern Medicine" (Milroy Lectures. Succeeding lecture on February 28).

BEDSON CLUB, KING'S COLLEGE, NEWCASTLE-UPON-TYNE, at 6.30.—Dr. Olaf F. Bloch: "Some Scientific and Technical Applications of Photography" (Bedson Lecture).

Friday, February 24

ROYAL INSTITUTION, at 9.—S. Casson: "The Collapse of Ancient Civilization: a Study of Archaeological Evidence."

Saturday, February 25

SCHOOL NATURE STUDY UNION (at University College, London), at 3.—Annual Conference. E. G. Boulenger: "Behind the Sciences in the Zoo Aquarium."

ASSOCIATION OF TECHNICAL INSTITUTIONS, February 24-25.—Annual General Meeting to be held in the Hall of the Merchant Taylors Company, Threadneedle Street, London, E.C.2.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

LECTURER IN CHEMISTRY in the Dudley and Staffordshire Technical College and Dudley Training College—The Director of Education, Education Offices, St. James's Road, Dudley (February 20).

ASSISTANT (grade III—refrigeration) in the Ditton Laboratory, East Malling, Kent—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (February 22. Ref. J 29/3).

LECTURER IN METALLURGY in the County Technical College, Wednesbury—The Director, Secondary and Technical Department, County Education Offices, Stafford (February 23).

ASSISTANT FOR RESEARCH IN HOP DISEASES—The Secretary, Hop Disease Investigations, c/o East Malling Research Station, Maidstone, Kent (February 25).

PROFESSOR OF MECHANICAL ENGINEERING in the Manchester Municipal College of Technology—The Principal (March 4).

ASSISTANTS (grades II and III) in the Meteorological Office—The Under-Secretary of State (S.S.B. (Met.)), Air Ministry, Admiralty House, Kingsway, London, W.C.2 (March 4).

LECTURER IN HUMAN PHYSIOLOGY in the University of Manchester—The Registrar (March 6).

SENIOR JUNIOR OBSERVER in the Solar Physics Observatory, Cambridge—The Director (March 7).

ASSISTANT LECTURER IN MATHEMATICS in the University of Manchester—The Registrar (March 11).

DIRECTOR OF THE COMMONWEALTH SOLAR OBSERVATORY, Mount Stromlo, Federal Capital Territory—The Office of the High Commissioner for Australia, Australia House, Strand, London, W.C.2 (March 15).

PHYSICAL CHEMIST in the Chemical Research Department, Dunlop Rubber Co., Fort Dunlop, Birmingham, 24—The Director.

SENIOR LECTURERS IN BACTERIOLOGY, PATHOLOGY AND ANIMAL HUSBANDRY in the Royal (Dick) Veterinary College, Edinburgh 9—The Secretary.

ASSISTANT INSPECTOR under the Alkali, etc., Works Regulation Act under the Department of Health for Scotland—The Secretary, Edinburgh, 2.

Science and Democracy

A MANIFESTO on the relation of science to present developments in the international political situation has been issued on behalf of American men of science by a committee, of which Prof. Franz Boas of Columbia University, the doyen of American anthropologists, is the protagonist. It is a document which is no less remarkable for the extent and character of the support it receives, in view of conditions in the United States, than for its argument. It is signed by 1,284 scientific workers, including three Nobel Prize winners, Prof. Harold C. Urey of Columbia University, Prof. R. A. Millikan of the California Institute of Technology, and Dr. Irving Langmuir of the General Electric Company, Schenectady, N.Y. The signatories are drawn from a hundred and sixty-seven universities and research institutes, and include eighty-five college presidents, deans, and directors of industrial laboratories and experimental stations; sixty-four are members of the National Academy of Sciences.

The signatories call upon their colleagues to participate actively in the defence of democracy as the sole means of preserving intellectual freedom and insuring scientific progress. It is perhaps unnecessary to recall that, as the oldest and the greatest of existing democracies, the people of the United States cherish as their proudest and dearest political possessions the right of free thought, the right of free speech, and the rule of the majority. These are for them, as they have been for all free peoples (at least of modern times) the fundamental conditions of truth and justice, and as such the basis of free and democratic institutions. The aim of the manifesto is, broadly speaking, to demonstrate, and to urge upon all scientific workers the duty of showing to the people of the United States that the development of political

theory and practice in the totalitarian States cuts at the root of these principles, and at the same time at the freedom of all mankind, as well as endangers the possibility of the advancement of man's well-being through the ministrations of science.

In demonstrating the relation of science to freedom of thought and speech under democratic institutions, the manifesto takes its stand on the recent resolution of the American Association for the Advancement of Science. "Science", it was there said, "is wholly independent of national boundaries and races and creeds and can flourish only when there is peace and intellectual freedom." "If science", the manifesto goes on to say, "is to continue to advance and spread more abundantly its benefits to all mankind, then the man of science has a moral obligation to fulfil. He must educate the people against the acceptance of all false and unscientific doctrines which appear before them in the guise of science, regardless of their origin."

Further, the Fascist position towards science is publicly condemned. It is shown to have violated both truth and justice in the most profound sense by the imposition of scientific theories and doctrines which have been demonstrated time and again to be false, and by debarring a section of the population, Jews or 'non-Aryans', from intellectual and scientific activity; while the "thousands of teachers and scientists who have been exiled . . . bear testimony to the incompatibility of Fascism and science". The manifesto in this connexion goes even further and regards "the attack on freedom of thought in one sphere, even as non-political a sphere as theoretical physics, as in effect an attack on democracy itself. When men like James Franck, Albert Einstein or Thomas Mann may no longer continue their work, whether the reason is race, creed, or belief, all mankind suffers the

loss"; and it concludes, "If we American scientists wish to avoid a similar fate, if we wish to see the world continue to progress and prosper, we must bend our efforts to that end now."

The action of American men of science in issuing this manifesto on the relation of development in the international situation to the progress of science has fallen at a singularly opportune moment; and its implications will not escape the notice of their colleagues in the countries of Europe. Unquestionably it has been to the advantage of the intellectual advancement of the world at large that, while in the political sphere the United States of America has held fast to isolation as a corollary of the Monroe Doctrine—a policy now for the second time within the present century under public consideration in view of danger to democratic institutions—that isolation has not been a characteristic of this great people in matters of the spirit, more especially in the development of the arts and in science. By free exchange and interchange of ideas and personnel, the New World has

co-operated with the Old to their mutual benefit; while the recent approach of the American Association for the Advancement of Science to the British Association, for the promotion of joint consideration and discussion of problems of scientific import and socio-economic application, opens up further prospects of an accelerated movement towards world unity in attack on those broader questions in which science touches the interests and well-being of mankind as a whole. Notwithstanding differences in social conditions between the United States and the countries of the Old World, which would militate against either the utility, or perhaps even the possibility, of like action in the very different circumstances prevailing in the European democracies, nevertheless the pronouncement of American men of science inculcates a principle in its statement of the relation of scientific progress and democratic institutions, which may well be laid to heart; and it is of no less importance that once more it has demonstrated in practical form the essential solidarity of the world of science.

The Census and the Distribution of Population

EVERY civilized community needs a full and accurate knowledge of its human resources; and hence the census has developed far beyond its primary function of merely numbering the people. It has become a periodic stocktaking; and among other aims it should provide precise and full information about the distribution of the people within a country.

Every person is counted at the place in which he, or she, is at the date of the census. This gives the first facts of the distribution, what is called the *de facto* population of each census district and of the country. In the past this has been considered sufficient, provided that the actual census could be carried out within a very short time, so short that no appreciable movements took place during the count. Up to 1921, it was the only distribution directly recorded by the census in Great Britain. But in that year the count was made in June, instead of in April as usual; and the holiday movements which had then begun caused serious uncertainties in the results as compared with those of other censuses and with intercensal estimates. Hence in 1931 there was introduced a question requiring each person to state his usual, or legal, place of residence.

This made it possible to count the regular inhabitants of each district, and so to measure the *de jure* population, by excluding visitors and including temporary absentees, a second stage in an accurate measure of distribution. The difference between the *de facto* and the *de jure* populations may at some places and times be considerable, especially in a holiday resort such as Blackpool; and it is obviously necessary to know the numbers of the resident population for many purposes of administration. The counting of the *de jure* population has always been the aim of censuses taken to determine electoral constituencies, as in the United States of America; it is surprising that it did not come earlier in Great Britain.

The requirement that each person shall state his place of birth enables the census to obtain some information regarding the origins and migrations of the people it enumerates. It is regrettable that the separation of Eire from the United Kingdom in 1922 has been allowed to interrupt the continuity of the records under this head. This can be avoided for the future if under 'birth-place' in the schedule we write 'British Isles' in place of 'United Kingdom'; and so obtain records

comparable with those of censuses before 1922, without losing anything in comparisons with that of 1931. A large part of the recent immigration into Great Britain is from Ireland; and fuller information about these immigrants is much to be desired.

In relation to the birthplace question, however, the chief desideratum is a fuller analysis and tabulation of the results. In 1931, for each administrative county and every town in England and Wales with more than 50,000 inhabitants, the census tables classed the numbers of those enumerated there into those born in that district, those born elsewhere in England, elsewhere in Wales, in Scotland, in Northern Ireland, or in any one of many other countries. But if the classification is to give information about migrations within England, 'elsewhere in England' is a useless grouping. To measure the 'drift to the south' it should be replaced by at least the county of birth of each person enumerated, for the whole of Great Britain or, preferably, for the British Isles. Also these migrants should be classified by age and sex, and perhaps also by occupations, so as to give a measure of the character of the migration. It is clear that to do this will involve much more detailed analysis and tabulation of the results. But the magnitude of the internal movements of our population has been so great in recent years, and its results are of such importance, as to justify a demand for the fuller and more precise knowledge of it which can only be obtained in this way.

Another important group of population movements is that of the daily journeys between residence and workplace. We all know that the day and night populations of many districts differ widely; but this knowledge is rarely precise. In 1921 the census schedule included a question on workplace, the answers to which gave valuable information on this daily ebb and flow of a large part of our population. The question was omitted in 1931; and only partly replaced by the requirement that each employee should state the address of his employer, which is usually the place at which he works. Thus, for 1931, this information is available for only a part of the population. The question should be restored for 1941, and applied to every person engaged in regular work. The importance of a knowledge of this daily movement for the planning of suburban transport, of roads, and of housing, and for other local government purposes, is quite obvious and

sufficient to justify the cost involved in obtaining and tabulating the information.

Recent changes in the distribution of the population in Great Britain have been considerable. The 'drift to the south' (actually towards London and some parts of the Midlands), though it may have been exaggerated and misunderstood in the popular imagination, is a real and important fact. Such migrations, among a people whose numbers are no longer increasing to any considerable extent, involve actual decreases in the population of some other parts of the country. Before we can know the real importance of these movements or take any reasoned steps to deal with them, it is essential to have much more exact knowledge of their extent and range. In what numbers and in what proportions do the migrants come from the distressed areas, from highland areas, or from the rural areas and small towns? Do they spread themselves widely, or do they tend to move and settle in groups? There is urgent need for trustworthy answers to these and other questions concerning the migration; and a fuller analysis of the census returns can provide much material for the answers.

In England the census has provided from time to time, but never for all at the same time, information concerning four groups of facts relating to the distribution of the people. The first of these is the number of the *de facto* population of each census district at the time the census is taken. The second, begun only in 1931, is that of the *de jure* population, at its usual residence, for the same date. The third comes from the comparison of the first, or in future of the second, with the information as to birthplace, age, sex, and occupation; it gives a measure, necessarily incomplete but nevertheless of real value, of internal migrations and of immigration. The fourth group of facts relates to the daily, or other short-period, movements.

The importance of a knowledge of all these facts of distribution has been emphasized recently by considerations of air raid precautions and of civilian defence. A thorough knowledge of the normal distribution of the people is necessary for efficient defence in war, and not less so for any adequate national planning for times of peace. It is, therefore, very desirable that the coming census of 1941 should be used to obtain the fullest possible information about all four groups of facts relevant to the distribution of the population of Great Britain.

Ancient Hindu Algebra

History of Hindu Mathematics:

a Source Book. Part 2: Algebra. By Bibhuti-bhusan Datta and Avadhesh Narayan Singh. Pp. xvi + 314. (Lahore: Motilal Banarsi Das, 1938.) 7.8 rupees; 13s.

THIS is the second volume of the three in which the authors are writing the history of Hindu mathematics. The first contained Part 1, dealing with numeral notation and arithmetic, which was issued in 1935, and noticed in NATURE of January 18, 1936, p. 88; the present volume (Part 2) contains the history of algebra.

Historians of mathematics have hitherto been handicapped in describing the course of development of Indian mathematics because they have generally been dependent upon a few special studies such as H. T. Colebrooke's "Algebra with Arithmetic and Mensuration from the Sanscrit of Brahmagupta and Bhaskara" (1817) and new editions of that work, "Notes on Indian Mathematics" of various dates by G. R. Kaye, a study by the same scholar of the Bakhshārī manuscript, and a few original texts and German or English translations, mostly brought out in India and so not generally accessible. But the published material is small compared with the extent of the sources. The editors' bibliography in Part 1 contains some thirty-eight items setting out the various books and MSS. to which they have had recourse, and from which they have translated in full a vast number of passages. They estimate that about half the content of this second volume is here presented for the first time, so that the future historian will have at his disposal copious material as never before.

The volumes are definitely source-books, and in consequence by no means easy reading. One characteristic of the Indian mathematicians is the careful formulation, *in extenso*, of rules for the solution of every type of algebraical problem (whereas the remains of the ancient Egyptian and Babylonian mathematics contain a multitude of examples, but practically no expressed rules). The rules have all to be expressed in words because the Indian had practically no symbols; the unknown was "yāvat-tāvat" or "avyakta", and was denoted sometimes by a blank with the number representing the coefficient following it, sometimes by abbreviations for the names of various colours, sometimes by letters of the alphabet; signs for operations were limited to + (after the symbol to which it relates), or a superposed dot or small circle, for minus, the others being abbreviations for words;

powers were 'square', 'cube', 'square-square', 'square-cube', 'cube-cube', so that the Indian symbolism had not even in Bhāskara II's time (twelfth century A.D.) advanced beyond the stage represented by Diophantus (third century). It is not surprising, therefore, that the statement of a rule for solving an equation or a set of equations sometimes runs to many lines, equal to a third or a half of the printed page, in one of these volumes.

The subjects include (besides technical terms, laws of signs, fundamental operations, etc.) linear equations in one, two, or more unknowns, quadratic equations, single and simultaneous, a few equations of higher degrees, indeterminate equations of the first degree, simultaneous equations of the first degree, the solution in integers of the equations $Nx^2 + 1 = y^2$ ('square-nature') and $Nx^2 \pm c = y^2$, general indeterminate equations of the second degree, rational right-angled triangles, rational quadrilaterals, linear functions made squares or cubes, double equations of the first and second degrees, and finally the solution of the equation $ax^2 = bx + cy + d$.

The genius of the race for the theory of numbers brought the Hindus by A.D. 1150 to their supreme achievement, the general solution in integers of the indeterminate equation of the first degree in two unknowns and of the famous (miscalled) "Pellian" equation. The first was solved by the method called the 'pulveriser' ('kuṭṭaka'), and the stages through which the solution passed are represented by Aryabhata I (born A.D. 476), Bhāskara I (522), Brahmagupta (628), Mahāvīra (850), Aryabhata II (950), Śrīpati (1059) and Bhāskara II (1150). The editors give the rules stated by each of these writers. The importance attached by the ancient Hindu mathematicians to the method of the 'pulveriser' is attested by the fact that the whole science of algebra was once named after it ('kuṭṭaka-gaṇita', the science of 'kuṭṭaka'). Still more remarkable is the solution in integers of $Nx^2 + 1 = y^2$ (the 'square-nature'). The account begins with Brahmagupta's Lemmas, rediscovered by Euler in 1764 and by Lagrange in 1768, and finishes with the 'cyclic' method described by Bhāskara II (1150). Fermat, Brouncker, Wallis and Euler could do no more than rediscover what the Hindus had given, and only Lagrange supplied the final proof that the 'cyclic' method will in every case produce the desired result whenever N is a number which is not a square.

The book has evidently involved untold research and labour, and cannot be too strongly commended.

Physics in College and School

(1) **T**HE first of the books under notice presents a clear and well-arranged exposition of the foundations of the mathematical theory of electricity and magnetism. It covers the usual ground in electrostatics, magnetism and electrodynamics; and there is an appendix on the equations of Lagrange and Maxwell. Vectors are introduced and used from the beginning. The book is intended for students of electrical engineering at the University of Brussels and, in consequence, more attention than usual is paid to applications of all kinds. The book may be recommended to honour students, who would find the simple and detailed explanations useful.

(2, 3, 4) The next three books in the list are alike in many ways and the title of 'college physics' would apply to them all. They all provide a good

conspectus of the subject; they all assume considerable knowledge on the part of the reader; and they all give something more than a glimpse of the work which awaits a future specialist. In the United States, science is usually presented to the young in a very liberal manner. In these books, the authors consolidate the ideas which the students should have acquired and they carry the story much further. In every case, the books could be used with advantage by those who are preparing for higher school certificate examinations. A further point of resemblance is that the mathematics connected with the work is kept on an elementary level, though Prof. Alpheus Smith introduces the methods of the calculus in some useful appendixes. Now for the differences:

Prof. Perkins uses the language of mathematics freely, for he believes that most students find a concise symbolic treatment easier to grasp than a verbal one. He strongly emphasizes the quantitative aspects of the subject and rather avoids its applications to everyday life. The latter he leaves to the teacher, while he himself endeavours to make his text so clear that the students may understand the physical principles without further assistance. His book is better suited to the future specialist than to one for whom physics will not be of absorbing interest in after life.

Prof. Caswell goes to the opposite extreme. Taking the view that most of the students who use his book will never take a more advanced course in physics, he includes a great deal of illustrative material, the result being that the space which remains seems scarcely sufficient for the orderly presentation of his subject. For example, within the first thirty pages of his text, he defines conservation of energy, mass, vector quantity, gram-molecular-weight, electrons, protons, atomic number and valency; which certainly is quick going.

Prof. Smith steers a middle course by keeping the logical development of his subject in the foreground, while providing a wealth of illustrative matter in small type. Thus the continuity of thought is not broken, but the work is lightened for the student and reality is lent to the whole. In this, the fourth edition of Prof. Smith's work, he has introduced a separate chapter on nuclear physics and has added one on astrophysics.

(5) Mr. Bray's book is a straightforward work with certain pleasing features, one being the insertion of many historical notes. In this edition, the chapters on photometry and spectra have been rewritten in accordance with the progress which

has been made during the last decade. The scope of the work may be indicated by saying that it concludes with a selection of questions taken from higher certificate and university entrance scholarship examinations.

(6, 7, 8) The remaining three books are concerned chiefly with work at about the school certificate level. Many teachers will be glad that Mr. Pearce has followed up his "School Physics" with a "School Electricity", for he writes clearly and his book is beautifully produced. The final chapter on modern developments should incline many students to continue their study of physics.

Mr. Shackel's book is the second part of his "Concise School Physics". It is a worthy successor of the first part, "Mechanics", on which an appreciative comment was made in *NATURE* on September 24, 1938, p. 551.

Finally, Messrs. Humby and Goddard's "A Complete Revision Physics, Notes and Questions" has already proved a useful tool in the hands of teachers during final revision for the school certificate, army entrance and kindred examinations. In the present volume, magnetism and electricity are added to the hydrostatics, heat, light and sound of the former one.

Animal Language

Animal Language

Described by Julian Huxley, recorded by Ludwig Koch and the Parlophone Company. Pp. xi+62+31 plates. (London: *Country Life*, Ltd., 1938.) With 2 Records, 21s. net.

ALTHOUGH the noises made by animals are among the most familiar sounds in Nature, they have seldom been the subject of serious biological or psychological study. The present work is an attempt to provide a clearer understanding of the significance of animal sounds than can be obtained by the perusal of an ordinary book. The publishers explain that a 'sound-book' of this type is the natural medium whereby text, picture and gramophone records form a natural unity in which the text comes to real life through the records and vice versa. Individual readers must judge, for themselves, how far this ambition has been fulfilled.

Preliminary inspection suggests that the book is well illustrated. In a sense this is true, but it is disappointing to find that few, if any, of the numerous illustrations are really relevant in the sense that they aid materially in an understanding of the text or in an interpretation of the records. The photographs, nearly forty in number, are no doubt interesting in themselves, but they are seldom attractive; the harsh contrast of tones produces, on some observers at least, a somewhat displeasing impression.

The text of the book is full of interest, for it reveals the paucity as well as the extent of our knowledge. Dr. Huxley covers the whole animal kingdom in his survey and has collected together a wealth of otherwise scattered information. It is sad to find that we must abandon our belief in the soothing influence of the snake charmer's pipe, but it is comforting to think that the ears of the common female frog may lead her with some

certainly to the embraces of that male whose individual song is best attuned to her own fancy.

The interpretation of animal sounds is a fascinating but difficult subject, and it is therefore unfortunate that the evidence in support of Dr. Huxley's views is seldom presented in sufficient detail to enable the reader to form an independent judgment. At times, Dr. Huxley expresses his own views with considerable confidence. "What is the point of a rattle-snake's rattling? The answer is really very simple. The snake doesn't want to strike unless it has to. It might very easily get trodden on. . . . The rattle is a warning to the intruder to keep away. . . . In the same sort of way those who instal burglar alarms in their houses put up a notice to that effect outside." This may be so, but whether it is an established truth or simply an *ad hoc* hypothesis we are given no real evidence to decide.

The text of the book is of very considerable length, and one reads on in the hope of reaching eventually a detailed consideration of the gramophone records. Unfortunately, one is doomed to disappointment, although the records themselves present unique material for the study of 'animal language'. The first record is composed of isolated sounds from a variety of mammals; most of them are associated with anger, food or sex. Each section of the record must be played several times in succession before it yields its full flavour; it is, however, well worth while to educate one's ear to the 'gurgling' of a satisfied Arabian camel or to the 'whispering whinny' of an amorous panda. The 'African night' record is definitely exciting particularly if played out of doors on a dark night.

The book is extremely well produced, and one gets the impression that a closer liaison between the three authors would have avoided some of the limitations to which this review pays, perhaps, too much attention.

Electrode Potentials

The Electrode Potential Behaviour of Corroding Metals in Aqueous Solutions

By O. Gatty and Dr. E. C. R. Spooner. Pp. xi + 504. (Oxford: Clarendon Press; London: Oxford University Press, 1938.) 25s. net.

MUCH in electrochemistry is controversial, and fresh outlooks and ideas are exceedingly stimulating. This book is justified by the ingenuity of speculation advanced, quite apart from the very considerable amount of data, largely original, presented upon the electrode potential characteristics of a large number of the more important metals.

The arrangement is certainly unorthodox for a work which may well be considered standard, but the context falls easily into the collection of papers presented, and is quite easy for reference even if it does suffer from the lack of a subject index.

A large introductory paper deals with theory: it is well arranged, comprehensive, often original in outlook, and rich in references. There follows, in a number of papers, a treatment of the specific behaviour of many metals; very clear descriptions of the experimental technique adopted are given,

and the analysis and discussion of phenomena presented are critical.

In particular, the paper on iron should receive mention, from the importance of the metal, and from the comparative length of the treatment given. It outlines work published upon behaviour, stresses the importance of the time factor in potential measurement interpretation, and elucidates much concerning the nature of the corrosion of iron, passivity, the effects of solute nature, pH, temperature, grinding, oxygen diffusion, etc. It is exceedingly clear upon the mechanism whereby the inhibition of corrosion is effected by chromates.

There are a number of appendixes of some length, forming a not unimportant part of the whole. One treats with very recent work in over-voltage, some of which has not otherwise been published. Another deals with developments in the theory of tarnishing, applications of which to the treatment of silver, copper, and aluminium bronze, have much promise.

This book is of very definite utility to electrochemists and corrosion chemists, and should be of considerable interest to many others. A. J. G.

Fingerprints

Fingerprints:

History, Law and Romance. By George Wilton. Pp. xix + 317 + 10 plates. (London, Edinburgh and Glasgow: William Hodge and Co., Ltd., 1938.) 12s. 6d. net.

THE central topic of Mr. Wilton's book on fingerprints is the claim of Henry Faulds (1843-1930) to have been the originator of the use of fingerprints in criminal identification and detection. In 1880 a letter appeared in *NATURE*, (22, 605; Oct. 28) from Faulds, a medical missionary in Japan, stating that his study of fingerprints, initiated by his observation of impressions on Japanese prehistoric pottery, had led him to the conclusion that bloody impressions on clay, glass, etc., might lead to the scientific identification of criminals. In a later issue of *NATURE* of the same year (23, 76; Nov. 25), Sir W. J. Herschel wrote to point out that he had used fingerprints in India for more than twenty years.

Mr. Wilton traces the subsequent history of the study of fingerprints in relation to criminal identification and the introduction of the fingerprint system of identification of habitual criminals

in English police work. The part played by Sir Francis Galton in the matter is consistently and sometimes violently attacked. While Mr. Wilton's use of the documentary evidence is not unfair, his championship of Faulds leads him to take an unduly harsh view of Galton's undoubted neglect of Faulds's work. On the other hand, there can be no doubt that it was through Galton's work and influence alone that the police authorities adopted the system, which was introduced by Sir E. Henry at Scotland Yard in 1901.

Had Mr. Wilton a closer acquaintance with conditions at the time, he could scarcely have maintained that Faulds's work affected the issue in the slightest. Priority of publication undoubtedly belongs to Faulds; but it was Herschel's practical experience in India that influenced Galton; and it was Galton's work, especially in the classification of fingerprints, and his prestige as a man of science that was responsible for the substitution of the fingerprint for the anthropometric system which had been adopted by the police on the model of the Bertillon system in the latter half of the nineties of the last century.

La fluorescence en biochimie

Par Prof. Ch. Dhéré. (Les problèmes biologiques, 21.) Pp. xii+318+27 plates. (Paris: Les Presses universitaires de France, 1937.) 80 francs.

IN some respects this treatise may be regarded as a counterpart of the same author's contribution to Abderhalden's "Handbuch der biologischen Arbeitsmethoden" reviewed in NATURE in 1935. However, it is by no means a translation, for the arrangement is different, and much of the matter has been brought well up to date; indeed, the author (p. xi) distinguishes between the two works.

The treatment is concise and eminently practical, throughout, and anticipates possible experimental difficulties on the part of the inquirer; for example, on p. 233, the author, speaking of hæmatoporphyrine in pyridine, leads the reader from the first impression that there is only one fluorescent band to the discovery that there are really two. Apparatus is described in detail. The main themes of practical interest to the biologist are dealt with in separate chapters, where each receives such comprehensive treatment that few readers will fail to gain either the information or the guidance they need; for example, those on glucides, fats, proteins, alkaloids, chlorophylls, bile pigments, vitamins, microbes, each with its own bibliography; these occupy 250 pages. The present reviewer does not recall the toluene experiments attributed to him (p. 69); his own more recent work, as yet unpublished, makes him critical of any observations on the fluorescence of the sugars, including his own earlier work, unless the material has been rigorously purified; hence the data on pp. 65-68 should be read with discrimination.

The book is not burdened with much theory, but it discusses at some length spectroscopic aspects of the subject. It is furnished with fifty-two figures in the text, and a further fifty-six, mainly spectrograms, in twenty-seven plates. The book as a whole is well produced.

S. JUDD LEWIS.

A Systematic Review of the Genus *Phylloscopus* (Willow-Warblers or Leaf-Warblers)

By CLAUD B. TICEHURST. Pp. viii+193+2 plates. (London: British Museum (Natural History), 1938.) 10s.

DR. TICEHURST has for long been recognized as an authority on the willow-warblers, and this critical revision of that group is a model of what such a work should be. He has based it primarily on his own examination of thousands of specimens available in museum collections, and only secondarily on the previous literature. By his determination, there are thirty species in the genus and these comprise, in all, sixty-seven separable forms. They are distributed across Europe and Asia, the largest number of forms being found in the mountain ranges bordering the Tibetan plateau: two are strangely isolated on the islands of Flores and Timor.

Of the three which breed in the British Isles, the ordinary willow-wren and the chiffchaff are scarcely distinguishable by sight under ordinary field conditions, although their songs are strikingly different, and this is indicative of the difficulty of the group as a whole. The complexity is increased by the fact

that allied species show parallel variations in corresponding parts of the area which they jointly inhabit; but this is itself one of the points of general biological interest which emerge in the present study.

Most of the forms are migratory, and although information as to winter ranges is in many cases still far from complete, the general trends are becoming clearer. One form which breeds only in north-eastern Siberia winters in Africa, and one with a breeding range extending as far west as northern Norway does not winter nearer there than Siam: these two movements, the greatest exhibited in the group, cross each other at right angles.

The book includes useful sketch maps illustrating distribution and migration; the two coloured plates by Mr. Roland Green show eleven species of which no plate had hitherto been published.

Index Kewensis Plantarum Phanerogamarum

Supplementum 9: Nomina et Synonyma omnium Generum et Specierum ab initio anni 1931 usque ad finem anni 1935 nonnulla etiam antea edita complectens. Ductu et consilio A. W. Hill. Confecerunt Herbarii Horti Regii Botanici Kewensis Curatores. Pp. iii+305. (Oxford: Clarendon Press; London: Oxford University Press, 1938.) 84s. net.

ONLY five years have elapsed since the publication of Supplement 8 to the "Index Kewensis" and in Supplement 9 botanists are presented with a volume considerably larger than any of its immediate predecessors. Since the first appearance of the "Index" in 1893—made possible by the munificence of Charles Darwin—the publication of each Supplement marks a stage in the progress of systematic botany, and provides the only authoritative list of the names of plants recently described, the author and place of publication of each, together with an indication of the geographical distribution. Of the many important works which emanate from Kew none is so indispensable to botanists in general and to systematists in particular.

The present work is essentially what it sets out to be—an index, and its general plan follows that of earlier Supplements. The size of the volume is some indication of the large amount of work which has been accomplished in the systematic study of Phanerogams during the years indicated on the title page. The new genera which have been described are shared among numerous families, but reference may be made to the considerable number of additions to Compositae, Gramineae and Orchidaceae, while students of so-called critical genera such as *Capsella*, *Rubus*, *Hieracium* and *Taraxacum* will find a large number of new specific names for their consideration.

In the preparation of a work of this kind it is unlikely that omissions will not occur, and in the present Supplement a number of entries refer to species which were described before 1931. There can be nothing but praise, however, for those members of the staff at Kew who have undertaken the compilation of the work and for the great care they have bestowed upon its preparation. The volume is sure of a warm welcome from botanists and horticulturists throughout the world.

J. R. M.

The 200-inch Telescope

By Dr. Walter S. Adams,

Director of the Mount Wilson Observatory, Pasadena, California

DURING the past few years, responsibility for the construction of the 200-inch telescope and the solution of its many problems has lain with the members of three committees organized to deal with various aspects of the project. Of these committees, the Observatory Council is the executive body making final decisions upon major questions which are brought to its attention, the Policy Committee considers general matters relating to the function of the telescope and auxiliary instruments and the future operation of the Observatory, and the Construction Committee deals with all technical subjects connected with the design and construction of the telescope. Both the Policy Committee and the Construction Committee report directly to the Observatory Council.

The membership of the Observatory Council, as at present constituted, consists of representatives from the Board of Trustees and staff of the California Institute of Technology and the director of the Mount Wilson Observatory. The members of the other two committees are from the staffs of the two institutions. Dr. Max Mason is chairman of the Policy and the Construction Committees, and since the death of Dr. George E. Hale has also been chairman of the Observatory Council. Dr. John A. Anderson is the executive officer of the Observatory Council with general charge over the optical and instrument shops, and until January 1, 1939, Captain C. S. McDowell was supervising engineer in charge of construction. The advice and assistance of numerous engineers and men of science throughout the United States have been utilized to advantage on many occasions and have been given most generously.

A review of progress on the 200-inch telescope naturally divides itself into three parts: optical figuring of the 200-inch and auxiliary mirrors; design and construction of the mounting and drive; and construction and erection on Palomar Mountain.

OPTICAL WORK

The present figure of the 200-inch mirror approximates closely that of a sphere with a radius of curvature of 111 feet. The disk was first shaped on front, back, and edges by grinding with coarse carborundum and the centre was then hollowed out to a depth of about $3\frac{1}{2}$ inches with the aid,

first of a 50-inch tool, and then of successively larger tools up to the full size of 200 inches. As the spherical figure was approached, finer grades of carborundum were used so that when optical tests became necessary only a few hours of polishing were needed to give the surface sufficient reflecting power. During the first stages of work upon the disk, the cylindrical holes on the back of the mirror and the large areas between the supporting ribs were filled with plaster of Paris, and after the face and back had been made parallel the 40-inch opening at the centre of the disk was closed with a glass plug weighing about one ton. The plaster of Paris was removed when the surface had reached nearly the required form, and the mirror was placed upon rubber pads which rest on the frame of the support system of multiple counter-weighted levers. The friction of these pads was required to neutralize the strong lateral pull of the grinding and polishing tools making contact over so large a surface, and for this reason the horizontal plates of the supporting system were not engaged. The optical tests, however, were made with the mirror vertical and balanced upon the support system just as it will be when in use on the telescope. Future optical work, including the parabolizing, will be carried on with the mirror resting upon the rubber pads; but these will be removed when the figuring is completed.

From the first the optical tests of the mirror proved to be most satisfactory. No change was seen in the figure when the mirror was tipped repeatedly from a horizontal to a vertical position or when it was rotated. Also no local deformations could be detected at the points of contact of the thirty-six individual lever supports. In fact, the support system was found to be performing quite as well as had been hoped by its designers. The length of the radius of curvature proved to be about two inches less than had originally been planned, but this slight difference, amounting to about one inch in the focal length, is far within the limits allowed for in the design of the telescope, and it is probable that no attempt will be made to reduce the amount through polishing. The surface was found to be reasonably free from zones, but a small amount of astigmatism was present amounting to about 0.1 inch in the optical cut-off at the centre of curvature. This

proved to be due to a slight deformation of the disk caused by the horizontal pads upon which the mirror rests, and is being corrected by a small amount of fine grinding after suitable changes in the supporting pads.

Although the final parabolic curve of the surface of the mirror will be only 0.005 in. deeper than the spherical curve, the area is so great and the

this mirror will be one of the next major undertakings in the optical shop. It is at present shaped on front, back, and edges, and the surface has been ground approximately flat. It is planned to figure the three auxiliary hyperbolic mirrors, one for the Cassegrainian and two for the coudé combination, by the method devised by Hindle, without the use of the 200-inch mirror. Four spherical mirrors,

each about 40 inches in diameter and with a radius of curvature of 25 feet, are being prepared for this purpose, two being very nearly completed. The mirrors will be used side by side in a clover-leaf pattern and provided with adjustments for bringing their centres of curvature into accurate coincidence.

A few figures are of interest as indicating the scale of the optical work on the 200-inch mirror. About five tons of glass have been removed in the process of shaping and figuring, and about 20 tons of carborundum have been used for grinding. During the polishing, about 50 pounds of rouge an hour is the average consumption with the full-sized tool, and but a small fraction of this material can be salvaged. As a result rouge has been purchased in quantities hitherto quite unfamiliar to dealers in optical supplies.

MOUNTING AND DRIVE

The major portions of the telescope mounting have been under construction during the past few years at the South Philadelphia plant of the Westinghouse Electric and Manufacturing Company. They were completed and shipped in October and have been transported to Palomar Mountain, where erection has been in progress since November. These parts include the tube, the north and south

members of the yoke, the two east and west members, each of which consists of three sections, which, when joined, form a 60-foot tube 10 feet in diameter, the declination bearings and the hemispherical south bearing of the polar axis with its oil pads. Several of the individual pieces weigh between 45 and 55 tons, and the total weight of the completed mounting will approximate

Fig. 1.

DRAWING SHOWING THE SIDE MEMBERS OF THE YOKE WITH THE TELESCOPE 'TUBE' BETWEEN THEM.

process of polishing so slow that it is planned to make most of the change through fine grinding and to leave but the final stages of the figuring to the polishing tool. This procedure has already been found successful in figuring the spherical curve.

Accurate tests of the parabolic figure of the 200-inch mirror will require the use, as an auxiliary plane, of the 120-inch mirror. The completion of

500 tons. The north and south bearings of the telescope are on oil films maintained under high pressure, while the declination bearings are of the ball type. At the present time the south member of the yoke has been placed in position on its bearings and the supports for the oil pads at the north end are installed in readiness to receive the section of the yoke which will form the journal supporting this end of the telescope. This feature of the mounting is a welded structure, shaped like a horseshoe, about 4 feet deep and 46 feet in diameter. It

was machined with the tips of the crescent under tension so that it will have an accurate circular form when carrying the weight of the telescope.

The large gear wheels, two for the right ascension drive and one for the declination, are 14 feet 3 inches in diameter, and are being cut and ground in the Pasadena instrument shop, where all the control mechanism is under construction. The driving control of the telescope will be electric with a five per cent range in rate, and the instrument will be provided with computing devices for automatic settings in position.

SOUTH AND SIDE MEMBERS OF THE YOKE AT THE FACTORY.

Fig. 3.

ERECTION IN THE DOME ON PALOMAR MOUNTAIN.

CONSTRUCTION AND AUXILIARY INSTRUMENTS ON PALOMAR MOUNTAIN

The dome to house the 200-inch telescope is 137 feet in diameter and has been built and erected. The building is of double construction throughout with an air space between the two walls and heavy insulation on the inner wall. The insulation of the steel dome is by means of aluminium foil set in panels 5 inches thick, which cover the entire interior surface including the 35-foot split shutter. It is expected that the daily temperature range

within the dome will not exceed 3 degrees. The outer shell of the dome is of monocoque construction, consisting of three-eighths-inch steel plates welded together and stiffened by an interior framing of girders and arches.

The dome weighs about 1,000 tons and is mounted on thirty-two trucks with spring adjustments and forged steel wheels. The rails are welded to avoid joints and have been ground to a bevel so that the motion of the dome gives very little vibration. The driving mechanism consists of two motors,

180° apart, which operate through reduction gears to turn rubber-faced driving wheels which are held by springs against the vertical flanges of the rotating dome. This design has proved effective, and the friction of the rubber faces provides a brake against rotation of the dome, by high winds.

A travelling crane with a capacity of 60 tons is attached to the main arches of the dome, and the platform for carrying the observer to the small turret in the centre of the tube at the prime focus of the telescope will also be supported by this part of the structure. The basement of the dome will contain the large aluminizing chamber, a number of offices, photographic rooms under controlled temperature, small physical and chemical laboratories and the pier of the large coudé spectrograph room. The electrical control boards are housed on a mezzanine floor, and above this but just below the level of the telescope mounting is the main observing floor.

It is essential in the case of the 200-inch telescope,

in which the field of sharp definition at the centre of the photographic plate is limited and the value of observing time is extremely high, that the observational programme be defined as accurately as possible through survey work and identification of objects with instruments having wide angular fields and great light efficiency. Two Schmidt telescopes have been planned for this purpose, one of which, with an effective aperture of 18 inches and a focal ratio of 2.0, has been in operation for about three years. It has been most productive in studies of nebulae and the discovery of supernovae. A second instrument of this type, with an effective aperture of 48 inches and of focal ratio 2.5, is now under construction. The 45-foot dome has been erected on Palomar Mountain and the 72-inch pyrex disk for the spherical mirror has been received from the Corning Glass Works. The figuring and support of the 48-inch Schmidt correcting plate, which will not exceed one-half inch in thickness, will present some interesting optical and mechanical problems.

The Cell Theory

Its Past, Present and Future

AMONG the important meetings held by the American Association at Richmond, Virginia, in December, were those dealing with the cell theory—its development, its present status, and its future possibilities. These meetings were in the nature of a symposium and combined the best thought of the three sections of the Association, on history, botany, and zoology, which collaborated in the programme.

Seven outstanding papers by eminent scholars were presented in two sessions, morning and afternoon of December 27. Those taking part were: Prof. L. L. Woodruff of Yale University; Prof. J. S. Karling of Columbia University; Prof. E. G. Conklin of Princeton University; Prof. G. A. Baitsell of Yale University; Prof. Paul Weiss of the University of Chicago; Prof. Franz Schrader of Columbia University; and Prof. C. E. McClung of the University of Pennsylvania. The discussion and attendance throughout were exceptionally good, more than a hundred and fifty being present at the afternoon meeting.

The morning session, which was devoted to historical aspects, brought some surprising results, especially as bearing upon the two men, Schleiden and Schwann, who up to the present day have generally been given most credit with respect to the origin of the cell theory, which they were

supposed to have enunciated a century ago [see also *NATURE* of February 18, p. 293].

There was apparent agreement in the scholarly papers presented by Profs. Karling and Conklin that the cell theory was projected some time prior to the appearance of the works of Schleiden and Schwann, that these two men added nothing either in content or in clarity with respect to the theory as such, and that they in fact lent support to a general view of cell formation which was completely erroneous.

Prof. Woodruff dealt with the preceding period and with the influence of the microscope. One hundred and seventy years before 1838, Robert Hooke had described little boxes or cells seen under the microscope, and from his day onward other significant observations on cells had been recorded by such men as Malpighi, Grew, Wolff, and Lamarck. With the beginning of the nineteenth century, the cell theory came into sharper focus and received fairly clear and explicit delineation at the hands of Mirbel (1802–1809), Dutrochet (1824), Turpin (1826), Meyen (1828–1838), Brown (1831), Demortier (1832), Purkinje (1835), Mohl (1835–1838), and Valentin (1838).

All these significant contributions preceded the works of Schleiden and Schwann. Why then, it was asked, have the two men been called the

founders of the cell theory? Why the amazing situation "that we still continue to call it after them"? It would seem, as suggested by Profs. Karling and Conklin, that bluff and brag on Schleiden's part entered very largely into the picture. He underestimated, ignored, or ridiculed really important contributions of predecessors and contemporaries, and thus gained a wholly unwarranted recognition; and Schwann borrowed from Schleiden's arrogant claims as to plant cells and applied the same views to animal cells. Prof. Conklin concluded his most interesting paper by suggesting that "it would be more accurate as well as more becoming to strike out of our literature these personal possession tags attached to important discoveries, such as . . . the cell theory of Schleiden and Schwann!"

The afternoon session of the symposium, devoted to the present and the future of the cell theory, developed what appeared like a cleavage in points of view between those who see the problem primarily in terms of physical forces (of surface tensions, physical pressures, and electrical attractions and repulsions), and those who hold that living matter exhibits certain characteristics (such as variability, selective direction, and unfoldment in a temporal sequence) which sharply differentiate the organic from the inorganic.

It was generally agreed that the organization of the cell is exceedingly complex and that there is still much to be learned about it. Yet, on one hand it was maintained by Prof. Baitsell that the difference between the organic and the inorganic is "not one of *kind* but merely of *degree of complexity*. . . . Since the same materials are used in both domains, they must conform to the same elemental patterns." Recent advances in cellular knowledge are due primarily to the work of physicists and chemists. Prof. Schrader, who was concerned chiefly with the present status of mitosis, asked for renewed consideration of a 'dynamic'

hypothesis. He suggested, however, that such a hypothesis meets with many difficulties which recent findings have by no means removed, and that it is a foregone conclusion that the final explanation will not be as simple as had once been thought.

On the other hand, it was pointed out by Profs. Weiss and McClung that, although "the cells derived from an egg have definite, innate capacities of their own . . . the fact that the individual cell can differentiate in a variety of directions but actually differentiates only in one, calls for factors which direct each cell selectively into its proper course. These factors, by their very nature, are super-cellular." They apparently derive from the organism as a whole and suggest the presence of "racial material in a linear order within the chromosomes. . . . Since living systems have unique phenomena of a higher order (than the non-living), like reproduction, metabolism, and consciousness, it is only logical to conclude that there must be units of a new order to explain them."

The participants in the afternoon meeting were in if necessary agreement that there is no sharp break between the living and the non-living. The progressive series of integrations does not stop at the molecular but continues to higher orders. Furthermore, the chemical elements found in the living orders, and their physical and chemical properties and interactions, are, it would seem, precisely the same as those found in the non-living orders. If there was difference of opinion, it appeared to be as to whether the integrations of a higher order (such as the cellular) could be completely explained in terms of principles derived from a lower order (such as the molecular), or whether, since the living orders have properties not found in the non-living, they must have their own peculiar units and be explained primarily in terms of those units. The future, it was held, should soon bring us closer to a resolution of such disputed questions. JOSEPH MAYER.

Obituary Notices

Prof. A. Smithells, C.M.G., F.R.S.

THE death of Prof. Arthur Smithells, on February 8 at the age of seventy-eight years, has removed from the world of science one of the most distinguished participants in the successful effort that has been made in the last half century to break down the barriers between a science too isolated and self-satisfied and a community too indifferent and unconscious of its own needs. No man could be more permeated than he was with a real reverence and enthusiasm for scientific work and achievement. His more intimate personal friendships were almost entirely with men of science, and his own work on

the structure of flame was marked by keen insight and exceptional experimental ingenuity and skill.

Smithells was trained at Owens College, Manchester, and went on to enjoy the pleasant life and invigorating mental atmosphere which Munich and Heidelberg offered to students in those days, returning to an assistant lectureship at Owens. But, at the early age of twenty-five years, he was called to the chair of chemistry at the Yorkshire College in Leeds, and there was faced with the responsibilities and opportunities of a provincial college which was aspiring to be a university, and of a school of chemistry in a great industrial centre. Then came a

division of his activities and a multiplication of interests. His distinguished presence and faculty for the vivid presentment of ideas in speech or writing, and his capacity for the formation of wise and tolerant judgments, won for him quickly the confidence of both academic and lay elements inside and outside the Yorkshire College, and his work in aiding its development into the University of Leeds, by way of the federal Victoria University, was of inestimable value. As a trusted member of Senate and Council, as pro-vice-chancellor and as chairman of the Board of Science and Technology, he placed himself unsparingly at the service of the University in a successful endeavour to collaborate in securing for it the best of university traditions, while maintaining and developing its special character as a school of applied science of international reputation.

In 'pure' chemistry, Smithells obtained the co-operation of his life-long friend, Julius Cohen, and that of his pupil, Dawson, for organic and physical chemistry respectively, and was largely responsible for the appearance of such names as Procter, Green and A. G. Perkin on the list of teachers and research workers in special departments of applied chemistry. His own lecture courses were admirably planned and delivered. Although of necessity so much diverted by claims of university statesmanship and administration, he worked for many years on the subject of flame structure. He became a fellow of the Royal Society in 1901 and president of Section B (Chemistry) of the British Association in 1907. His instinct urged the application of this branch of science to practice and led him to make contacts with the gas industry by a series of striking lectures and by productive conversations. One outcome was the foundation by the gas industry in 1910 of the Liversay professorship of coal gas and fuel industries in the University of Leeds as a memorial to Sir George Liversay, W. A. Bone becoming the first occupant of the chair. Another result was the formation of the Joint Research Committee of the University and the Institution of Gas Engineers, with Smithells as its first chairman. This Committee, unique at the time of its formation, has gradually increased the scope of its work, and Smithells was made its first honorary member a few weeks before his death. The Society of British Gas Industries too honoured him by election to its presidency in 1911.

Another way in which Smithells was anxious to see scientific training and method take its proper place in the arts of life was indicated by those activities which led to his appointment as honorary educational adviser on home science and household economics in King's College, London, where such ideas received more toleration than elsewhere and have since come into a well-deserved prominence.

In 1913 came a break in Smithells' activities at Leeds, arising out of the interest he had displayed in the training of Indian students. He was invited to go as special lecturer to the Punjab University, and accepted willingly since he was anxious to illustrate how, in his opinion, the subject of chemistry might be made to appeal to the mentality of

the Indian student and carry him from theory to practice.

His generous and peaceful soul, with its memories of student days in Germany, was greatly shocked by the outbreak of war in 1914; but, like many others, he felt impelled to help and, first as special lecturer in the Northern Command and later as chief chemical adviser on anti-gas training to the Home Forces, with an office at the Horse Guards and the rank of lieutenant-colonel, he rendered services which were recognized by the distinction of C.M.G.

In 1923, after a few more years at Leeds in the busy post-war period, Smithells resigned the professorship he had held so long in order to take up the congenial duties of the director of the Salters' Institute in London. There he was occupied in the selection of promising young graduates in chemistry who might receive the endowment of the Institute in a further carefully planned training which should fit them for responsible work in industry. His personal knowledge of, and friendship with, so many who counted in the universities and in the various chemical industries, and his powers of judging and advising young men were here invaluable, and he was actively occupied with the duties of this post until failing health dictated his retirement in 1937. It was during this period that he interested himself specially in the Institute of Chemistry and was president for the term 1927-30. He was Harrison lecturer in 1935. Manchester, the university of his studentship, and Leeds, that of his professorship, both conferred upon him the honorary doctorate of science.

In writing, as in speech, Smithells was both lucid and convincing. This was apparent in the accounts of his scientific work submitted to the learned societies and in his lectures. His letters were greatly valued by those privileged to receive them for the same qualities, with more intimate, human and humorous touches and occasional accompanying sketches of persons—often children, in whom he delighted. He could never settle down to the writing of a treatise or text-book, but the Oxford University Press published a collection of his addresses, under the title "From a Modern University", dealing with such subjects as "The Relation of Universities to Technical and Professional Education", "The University and Women's Work", "Professors and Practical Men" and "The Modern University Movement".

Arthur Smithells was the third son of James Smithells and Martha, the daughter of James Liversay. He was twice married—in 1886 to Constance Marie (daughter of F. Mawe) and in 1908 to Katharine (daughter of Arthur Booth), who survives him. He had two sons and one daughter by his first, and one son by his second marriage.

JOHN W. COBB.

Prof. Robert Wallace

PROF. ROBERT WALLACE, professor of agriculture in the University of Edinburgh from 1885 until 1922, died at Kincardine-on-Forth on January 16 at the age of eighty-five years. The chair of agriculture, the oldest in the country, goes back to 1790, and Wallace

and his three predecessors in office, all men of mark, between them filled it for 132 years, a rather remarkable record.

The second son of Mr. Samuel Wallace, who farmed in a large way in Dumfriesshire, Robert Wallace studied agriculture at the University of Edinburgh under Prof. John Wilson, a notable teacher, whose "Farm Crops" was long a standard work. From the University he returned to his native county to engage in the practice of farming, whence in 1882, at the age of twenty-nine years, he was called to be professor of agriculture at the Royal Agricultural College, Cirencester. Three years later he was chosen to succeed Wilson in the Edinburgh chair.

While under such notable teachers as Coventry, Low and Wilson, the agricultural classes at Edinburgh had attracted students from a wide field, there had been up to this time no development of a co-ordinated course in agricultural science. Agricultural students could, and frequently did, take the ordinary classes in chemistry, natural philosophy, botany, natural history and economics; but there were no courses relating these subjects to the practice of agriculture. Wallace, with characteristic energy, set himself to remedy this defect, and the immediate result was the establishment by the University of the B.Sc. degree in agriculture, the first to take the degree being the late Sir William Somerville, afterwards Sibthorpean professor of rural economy in the University of Oxford. At a later stage he was instrumental in obtaining endowments for the establishment of the Steven lectureship in agricultural entomology and of the Garton lectureship in Indian and Colonial agriculture.

The earlier years of the present century were a period of great development in agricultural organization and in agricultural education and research, both in Great Britain and in the Colonies, and the Edinburgh School of Agriculture, first in the field with a comprehensive course in agricultural science of degree standard, was called upon in an extraordinary number of cases to provide men to fill key positions in agricultural departments and in agricultural colleges. One has only to recall such names as Somerville, Middleton, Campbell, Greig, Gordon, Gilchrist, Seton, Milligan and Clouston—to mention a few—to indicate the extent to which the Edinburgh School has influenced agricultural development in the last forty years; and just as no trouble was too great for Wallace to get his former students placed, so nothing gave him more pride and satisfaction than the successes later achieved by them.

Throughout the greater part of the tenure of his chair, Wallace lived under the happy dispensation of the two-term (winter session) academic year, and for many summers he travelled widely to study agriculture under varying climatic conditions. India, Australia, South Africa, Rhodesia, the United States, Canada, Mexico, Egypt, Greece and Italy all came under investigation, and the fruits of his studies gave a refreshing quality to opening lectures and were embodied in many books—for he was an indefatigable and voluminous writer. His best

known book is "Farm Live-Stock of Great Britain", which, first published in 1885, has gone through many editions, and is still a standard work.

A fervid champion of a wide range of causes, Wallace could scarcely avoid achieving a state of variance with quite a number of people, but none who really knew him could fail to appreciate the essential kindness, the rare generosity of the man.

E. SHERRER.

Mr. J. O. Borley, O.B.E.

MR. J. O. BORLEY, who died at Bexley, Kent, on December 30, at the age of sixty-six years, had retired only a year or so before from the post of fisheries adviser to the Discovery Committee (Colonial Office), and was still an active member of that Committee. His interest in whaling and antarctic research dated from his membership of the original Falkland Islands Committee, the recommendations of which led to the splendid investigations carried out under the auspices of the Discovery Committee. Borley took a great part in the planning of these investigations and in their administration. His thorough grasp of practical problems and the soundness and sobriety of his judgment were of the greatest assistance in the negotiations which led up to the international regulation of whaling.

The success of his work on the whaling problem was, I think, largely due to his long and intimate experience of fishery research, for up to 1928, when he joined the Colonial Office, Borley's life-work was the investigation of fishery problems. He started his fishery career at Lowestoft in 1903 under the Marine Biological Association, which, at that time, was responsible for the English share of the international fishery investigations. In 1910, when this work was transferred to the Board (later Ministry) of Agriculture and Fisheries, Borley moved to London with his staff, and was associated with Dr. A. T. Masterman in the general direction of the investigations. During the Great War, he rendered valuable services to the Ministry and to the Restriction of Enemy Supplies Department in an administrative capacity, which earned him an O.B.E. in 1918. In 1921, after the reorganization of the scientific staff, Borley returned to Lowestoft to take charge of the new Fisheries Laboratory which had been set up there through the energy of Prof. J. Stanley Gardiner.

Borley's own scientific work was concerned mainly with the plaice and the plaice fisheries, on which he became an acknowledged authority of international repute, publishing many papers of great value on this subject. He was an extremely painstaking and thorough worker, and was never content until he could wring out the last drop of information from the elaborate biological and statistical data at his disposal. He took a very keen personal interest in the difficult question of the protection of the plaice fisheries, and worked amazingly hard on the Plaice Committee of the International Council to bring about some effective measure of international control.

It was, I think, a keen disappointment to him that the recommendations of the Plaice Committee of 1921 and of the Plaice Conference at Amsterdam in 1925 could not be put into operation. But he did not lose heart; he supported his staff in working out just alternative methods of coping with the overfishing problem, which bore their first fruit in the Sea Fishing Industry Act of 1933.

In addition to his papers on the plaice, Borley published in 1923 an admirable study of the bottom-deposits in the North Sea, and was largely responsible for a special investigation of herring-trawling carried out just before the Great War, on which we reported jointly in 1922.

Borley was a colleague of mine for many years, and no man could wish for a better. He was always helpful, always put the work first and himself second. His great knowledge and experience was always freely at the service of his colleagues. He was a

lovable personality, and inspired both affection and respect in all those associated with him in the work of the Fisheries Department, of the International Council for the Exploration of the Sea, and of the Discovery Committee.

E. S. RUSSELL.

We regret to announce the following deaths:

Prof. V. A. Karavajev of Kiev, an authority on the taxonomy and bionomics of ants, on January 7, aged seventy-five years.

Prof. J. P. McMurrich, emeritus professor of anatomy in the University of Toronto, on February 9, aged seventy-nine years.

Prof. N. V. Naasonov, formerly director of the Zoological Museum of the U.S.S.R. Academy of Sciences, on February 10, aged eighty-five years.

News and Views

The Linnean Society and National Parks

As a result of the discussion on the objects of national parks held by the Linnean Society of London on December 8 (*NATURE*, 142, 1087; 1938) and subsequent debates, the Society has adopted the following resolution: "The Linnean Society of London accepts the definition employed in the African Fauna Convention as an ideal for the preservation of Nature; but it knows that the term 'National Park' has been given to areas which for various reasons are unsuitable for inclusion within the definition,—e.g. too limited or situated too near populated areas. For such it recommends the setting apart within each Park of special nature reserves under proper control; and it would like all authorities with power over Parks to seek advice from such bodies of naturalists as are competent to give it." The definition given by the African Fauna Convention (H.M. Stationery Office. Treaty Series, No. 27. London, 1933) is as follows: "The expression 'national park' shall denote an area (a) placed under public control, the boundaries of which shall not be altered or any portion be capable of alienation except by the competent legislative authority, (b) set aside for the propagation, protection and preservation of wild animal life and wild vegetation, and for the preservation of objects of aesthetic, geological, prehistoric, historical, archaeological, or other scientific interest for the benefit, advantage, and enjoyment of the general public, (c) in which the hunting, killing or capturing of fauna and the destruction or collection of flora is prohibited except by or under the direction or control of the park authorities. In accordance with the above provisions facilities shall, so far as possible, be given to the general public for observing the fauna and flora in national parks."

British Dyestuffs: Award of the Perkin Medal

THE Perkin Medal of the Society of Dyers and Colourists has been awarded to Mr. James Baddiley, of Imperial Chemical Industries Ltd., "in recognition of his national services for the renaissance of the British dyestuffs industry through many important investigations in the field of colour chemistry conducted or directed by him". In the thirty years since its inauguration, the Medal has only been awarded eleven times—four times to Englishmen, three times to Germans, three times to Frenchmen and once to an Alsatian. In an address delivered after the presentation, Mr. Baddiley said that great progress has been made in dyestuffs laboratory technique, such as the use of X-ray diffraction methods for determining molecular structure, optical diffraction in the visible and ultra-violet bands, and cathode-ray refraction. In the dyeing of cotton, substantial advances have been made, particularly with regard to light fastness. In the direct cotton colour field constant research had been given to straight-chain poly-azo dyes with 2-5-7 aminonaphthol-sulphonic acid and its derivatives as end-component, and this line of research had led to the production of the Durazols, which are representative of direct cotton colours of high fastness to light.

The dyestuffs chemist, affirmed Mr. Baddiley, has shown his ability to meet the problems presented by new artificial fibres very promptly, by producing the Solacets, a series of truly water-soluble dyes, possessing high affinity and building-up properties and capable of being applied as though they were direct cotton dyes. In regard to pigments, Mr. Baddiley mentioned the invention of the phthalocyanines in I.C.I. laboratories; these, he said,

represent the last word in all-round fastness and in tinctorial properties. Turning to textile auxiliaries, he outlined the fundamental principles involved in the modern 'soapless' detergents, the success of which led to intensive research in long-chain chemistry and the production of many new interesting products of which the best known is Velan PF for producing water-repellent finishes resistant to laundering and dry cleaning. Among other advances associated with the dyestuffs industry, Mr. Baddiley referred to the colour film, the discovery of sulphanilamide, and the synthetic polymers.

Commerce and the Universities

THE question of the suitability of existing arrangements in universities for the training of undergraduates for commercial careers was recently investigated by a sub-committee of the Association of British Chambers of Commerce. This body, having examined the subject in the light of information collected from university appointments bureaux, professional bodies, individual firms and various chambers of commerce, drew up a short "Report on the Commercial Employment of Students with Degrees in Commerce". The report estimates at less than a hundred the deliberate annual recruitment of young graduates into commerce for the purpose of ultimately using them for the higher executive posts. These recruits are taken mainly by large concerns engaged in either manufacturing or retailing: no evidence was forthcoming of any appreciable recruitment to wholesale houses or shipping concerns. It appears that the recruitment of graduates on the business side is sporadic and exceptional and the firms which employ them make no special arrangements, such as are common on the industrial side, for their special training in business methods. The sub-committee considers that it would be advantageous to British commerce if a larger proportion of graduates were recruited, but that this will not be possible unless steps are taken to incorporate practical office and commercial experience in the university courses.

THE Association's Executive Council adopted the report and decided to circulate it with a view to a conference with representatives of the universities for discussion of the subject and for the devising, if possible, of a scheme of training in the operation of which the chambers of commerce would collaborate. The kind of collaboration envisaged is indicated by mention in the report of a sandwich system of six months in business alternating with six months of full-time university work, or a preliminary spell of work in business before entering a university, in which studies would be organized in two parts separated by another spell of business employment. The report has been coupled, not, perhaps, very appropriately, with the Spens Report on Secondary Education in a motion agreed to in the House of Commons on February 15 in favour of the Board of Education consulting local education authorities and others as to how far the recommendations in the reports should be carried into effect. Presumably the recommendation of the Chambers of Commerce will

be taken up by the Universities Committee of Vice-Chancellors and Principals. In the discussion in Parliament, the Board's attitude towards commercial training in secondary schools was summed up. From eleven to sixteen years of age, geography and mathematics may well be taught so as to arouse an interest in the world of commerce, and there is a real place for commercial training on broad lines after the School Certificate; the prejudice against commerce as unworthy to rank with more academic careers should be eradicated.

An Anatomist Analyses

THE editor of the *Lancet* has begun the interesting experiment of throwing open his journal to selected medical men in various occupations, so that they may express unfettered thoughts upon any subject they choose, under the title "Grains and Scruples". The first series of contributions, five in number, appeared in the numbers of December 1938 "from an Anatomist". They discourse on the alleged gradual but definite degeneration of the medical student, who in former days is said to have been far older, more mature, and more responsible than his successor; upon the disappearance of the old-fashioned schoolboy bug-hunter, and other topics familiar to the teacher of long standing. But years have coloured the outlook, for there are still keen schoolboy naturalists, and while maturity and responsibility are difficult qualities to assess, the records show that the age of entry has been rising instead of falling. In the old days, students entered the universities at years of indiscretion undreamed of now, and the writer knew a surgeon-admiral who as a student, having passed all his medical examinations, put in a year on a whaler, until he should attain the legal age of qualification. That cannot happen often in these days.

BUT more profound puzzles confront the "Anatomist", and he poses the recurrent problem of the persistence in many groups of animals of primitive, generalized types. If changing environments demand the evolution of more complex animals to meet the new needs, how is it that there have survived through aeons of time, apparently completely meeting the requirements without significant structural change, basic forms upon which the higher developments of the group are founded? As examples of these 'immature' forms which have not developed their potentialities, he gives the shark, the giant salamander, the tuatara lizard, the ostrich, and following Bolk's thesis of infantilization he would regard man as the permanent baby amongst mammals, emphasising that lack of structural specialization which is man's saving grace. Finally he makes a reasoned plea for linking man ancestrally with the pig. But here he controverts his own premises, for while rightly stressing the need for depending upon characters not liable to environmental adaptation, he selects as major resemblances, dentition and hair-covering, length of tail and colour, than which no mammalian characters are more liable to adaptive variation. He does not suggest

how the extremities of man are to be derived from those of the pig, but perhaps he would include the Devil amongst men.

Sir C. V. Raman, F.R.S.

IN 1928, Sir Venkata Raman published an account of the new radiation effect now generally known as the Raman effect, and the Indian Academy of Sciences, of which he is president, has had the happy idea of celebrating this and Sir Venkata's fiftieth birthday by the issue of a special commemorative volume. This volume, which contains thirty-eight papers, submitted from various parts of the world, opens with a brief biography of Sir C. V. Raman. The writer of this, whilst referring to the fact that Sir Venkata received his early training in physics at the Presidency College, Madras, unfortunately omits to mention how much the future Nobel prizewinner owed to the then head of the department of physics, the late Prof. R. Ll. Jones, who carried to India the traditions of the Cavendish Laboratory.

THE contributions to the commemorative volume deal with the many aspects of physics with which Raman has been associated. Only two papers have been submitted by workers in Great Britain: Sutherland contributes a theoretical paper establishing the connexion between the force constant, the internuclear distance, and the heat of dissociation of a diatomic linkage, whilst Angus gives a valuable critical survey of the Raman spectra of terpenes. From Prof. K. W. F. Kohlrausch's laboratory at Graz, which has played so prominent a part in the application of the Raman effect to chemical problems, there are ten papers dealing *inter alia* with asymmetrical phthalyl chloride, dimeric keten, cyclobutane-1:2-dicarboxylic acid and its derivatives, tetrolic acid and the nitro-group. Papers on analogous subjects have been sent by Bonino and Manzoni-Ansidei, Murti and Seehadri, Mizushima and Moreno. Hibben provides a striking statistical analysis of the trend of Raman effect research during the ten years since its discovery; he shows how the fuller theoretical understanding of the effect (1932-34) gave an impetus to experimental investigation and discusses the types of organic and inorganic substances which have received attention. The remaining papers are concerned chiefly with the other aspects of optics to which Raman and his students have devoted attention. The volume forms a noteworthy tribute to one who has done so much to further original research in India.

A New "Nomenclator Zoologicus"

THE preparation of a new "Nomenclator Zoologicus", announced in 1935, is now approaching completion. It constitutes an attempt to bring together the names of all the genera and subgenera in zoology that have been described from the tenth edition of Linnaeus, 1758, up to the end of the year 1935, with a bibliographical reference to the original description of each. It will also include the great majority of alternative spellings that have appeared during that period. Another feature that will, it is thought,

be found valuable for systematists relates to cases where a new name has been proposed for a homonym. In these instances a cross-reference is given under the homonym to the new name. It is estimated that the work will comprise some 225,000 entries, of which about 5,000 appear to have been omitted from all previous publications of this character. It is proposed to publish the work in four volumes of nearly 1,000 pages each, which it is hoped it will be possible to issue at intervals of about six months. The Zoological Society of London has already borne the whole cost of preparation (approximately £1,800), but the Council of the Society does not feel justified in incurring further expenditure in respect of this enterprise, which would involve an additional £3,600. However, with the aid of various grants from outside sources, the editor, Dr. S. A. Neave, has now been able to arrange for the printing and publication of the work. It is proposed to publish it at the low advance subscription rate of six guineas, postage included, for the four volumes, provided that a sufficient number of undertakings to subscribe can be obtained. If these are adequate, it is hoped to issue the first volume during the coming summer. Subscriptions should be sent to Dr. S. A. Neave, Imperial Institute of Entomology, 41 Queen's Gate, London, S.W.7.

'Modern Man' from Choukoutien, China

SKELTAL remains of 'modern man' of Upper Palaeolithic age have at last been found in material from the Choukoutien caves, near Peking, the now world-famous site of discovery of Peking man. This latest find is no more than was to be anticipated from the discovery here some few years ago of relics of palaeolithic man; and indeed it is overdue. The new material, it is stated in a dispatch from the Peking correspondent of *The Times* in the issue of February 21, is from the Upper Cave, and consists of the remains of seven individuals, who, it would appear, had belonged to one family—an old man, estimated to be more than sixty years of age, a younger man, two relatively young women, an adolescent, a child of five, and a new-born baby. Such a varied assemblage should in the ordinary course provide adequate material for arriving at a fairly close approximation to the racial character of the group; but it would appear that these skeletal remains are remarkably, and indeed unusually, diverse in character for so closely associated a group.

THE brain case of the old man points to a very primitive type, not far removed from Neanderthal man, although in other attributes he approaches European man of the Upper Palaeolithic period, while the facial characters suggest recent Mongolian types without, however, being identical with them. Of the two women's skulls, one presents resemblance to the Melanesian type of New Guinea, while the other is similar to that of the modern Bakimo woman. No features, however, occur among the modern population of North China which would justify attribution of an ancestry leading back to this population of the Upper Cave. Prof. F. Weidenreich

quoted as suggesting that the Upper Cave people may represent the ancestors of the Amerindian population in process of migration to the crossing from Asia to America. Among the numerous artefacts which have been found in association with the remains—stone and bone implements, perforated teeth, shells, and stones used for ornament—several can be traced to an origin varying from 100 to 200 miles away. This lends support to the view that these were a far-travelled people in a stage of further migration. Injuries shown by the skulls indicate that all the members of the group met with a violent end.

British Optical Instrument Display at World's Fair

THE British optical instrument industry, through the Scientific Instrument Manufacturers' Association, is exhibiting a cross-section of the products of the industry at the World's Fair, New York. Eighteen firms are participating, and the exhibit is arranged in four showcases each 8 ft. by 3 ft. 6 in. by 3 ft., also a series of showcases mounted in two panels 24 ft. by 3 ft. stretching from a centre piece formed of a large mass of optical glass, and two photo murals 16 ft. by 12 ft. with showcards let in. The exhibitor firms have regarded the exhibit from a 'prestige' aspect, and by mutual arrangement each firm has endeavoured to end a limited exhibit of its specialities selected so that there may be no overlapping. In other words, makers of theodolites, levels and microscopes are showing a complete range of products, but built up of several makes rather than various models by each maker for the same purpose. The display is very comprehensive. Both in appearance, finish and presentation it should at least equal anything that has hitherto been devised. It is impossible to refer in the course of a brief note to all the different exhibits. These comprise among the more standard types a course-setting bomb sight, aeroplane sextant, echo depth-sounder, Robbin Hill camera, survey lens or aerial camera, spectrograph, spectrometers, apparatus for measuring pressure in mines and dust counters, measuring microscopes, microtomes, prism binoculars, telescopes, photographic lenses and cameras.

Soil Erosion in Jamaica

SOIL erosion in Jamaica forms the subject of a bulletin (No. 17) issued by its Department of Science and Agriculture. The greater part of the cultivated land is situated on steep hill-sides, gradients of one in one being frequent, so that sheet erosion is the major problem. These slopes were originally covered by dense forest and undergrowth, the clearing of which has resulted in rapid loss of surface soil. The rate of loss depends largely on the crop grown. Bananas and coffee, for example, are comparatively widely spaced and are maintained under clean cultivation so that soil exposure is very serious, though the necessity for drains in the case of bananas somewhat alleviates the situation. Sugar-cane, on the other hand, is an excellent soil conserver as it has an elaborate root system and the trash deposited after tapping forms a protective cover. Of the less im-

portant crops the cultivation of yams, sweet potatoes, corn or ginger encourages erosion, but citrus causes little loss as the trees are usually left in the grass cover. Erosion is also promoted by the otherwise valuable system of forking the soil at the end of the dry season to facilitate the penetration of the first rains, and by the improper placing of drains. Other factors which contribute to the problem are the practice of short-period tenancy, which gives the proprietor little interest in conserving the fertility of his land, and the system of renting land for the production of one type of crop only. Some fundamental changes in the current agricultural practices will be needed if further loss of valuable soil is to be prevented.

Earthquakes Recorded in India, January-March, 1938

SEISMOLOGICAL information obtained in India is henceforth to be published quarterly as a separate bulletin. The first of these bulletins (*Seis. Bull.*, Jan.-March 1938, Government of India Meteorological Department, Delhi) has been received. It consists of reports from seven instrumental stations, and non-instrumental reports received at Poona. First is given a list of stations with their latitude and longitude to the nearest minute of arc together with other necessary information, and also a list of the instruments and their constants with which each is equipped. For the quarter, Agra records 56 shocks, Bombay 77, Calcutta 89, Colombo 47, Dehra Dun 13, Hyderabad 41, and Kodaikanal 61. The small number recorded at Dehra Dun may be due to poor instrumental equipment. Records for the observatories are separate, giving in each case date, component, phase, time received, period, amplitude, epicentral distance if determined, and remarks concerning the shock or the reception. The macroseismic evidence collected at Poona is valuable, personal observations numbering 62, 12 being from Dosh. The shock with most macroseismic effect was on March 14. It cracked property at East Khandesh, damaged property at Maheswar (Indore) and damaged property, injuring two children, at East Khandesh. Seismologists will be grateful to those concerned with the report for putting the data obtained in a manner convenient for reference, and for taking the important step of having it published at more frequent intervals.

An Electron Diffraction Camera

Messrs. W. EDWARDS AND CO., Allendale Works, Vaughan Road, London, S.E.5, have recently published details of their Finch electron diffraction camera intended for industrial research. This camera is of the type developed by Prof. G. Ingle Finch, who has done so much to improve the technique of electron diffraction. The camera uses a cold cathode discharge tube as a source of electrons. The fine beam, which is necessary for a sharp diffraction pattern, is obtained by using a series of diaphragms and by focusing the beam upon the screen with a magnetic coil. A useful feature is that both the diaphragm and specimen holders are standardized so that they will fit any of the six ports in the instru-

ment. Moreover, all the necessary adjustments of the diaphragm and specimen can be made *in vacuo* from the outside. The joints are ground and polished flats held in contact by the atmospheric pressure, a point of importance in routine work where quickness in changing specimens is essential. In this instrument the specimen can be exchanged and the system evacuated in a matter of minutes. Only one criticism—a minor one—can be made. The shape and size of the window are such that the eyes must be held quite close if the whole pattern is to be seen, and the screen is then rather near for comfortable vision. Suitable pumps are supplied, a variety of systems being available to suit individual needs, or a standard unit is made up ready for use. This instrument is noteworthy as it marks the entry of the diffraction camera into the industrial research laboratory, where it should yield valuable information upon metallic surface structure, to mention only one of the many possible industrial fields of investigation.

Energy obtained by Transmutation

MR. ROBERT D. POTTER, of 'Science Service', Washington, D.C., points out that the confirmation of the artificial breakdown of uranium announced in New York (see also *NATURE*, Feb. 11, p. 233) is in the direct succession of experiments carried out in recent years on the transmutation of the elements. For centuries, alchemists had dreamed of transmuting base metals into gold. It was imagined that enormous wealth would be at hand for the discoverer of this transmutation, and dire forecasts of the effects of this discovery were made, such as a complete revolution on the financial pattern of the world. We know that this transmutation has now been achieved for most of the known chemical elements. Transmutation's biggest result is the theoretical incentive it has provided for further physical researches. In a similar way, the dream of releasing the large amounts of energy locked inside atoms has been in the minds of men for many years. When the most efficient transformation of energy takes place in the atom of uranium so that a neutron can slip into it, the energy released is only one fifteenth of that required to bring it about. In fact, neutrons are so easily absorbed by all atomic nuclei that many of the neutrons produced with such poor efficiency will only go into atoms other than uranium. There need be little fear of an explosion in Nature due to uranium. The very heavy elements, in which such an energy release can be secured, occur only in very small amounts in the earth's crust. The release of atomic energy can only be achieved by direct experiment with this end in view and with elaborate laboratory apparatus.

Archaeological Discovery near Hove

A somewhat remarkable find of traces of what would appear to be an ancient settlement is reported from the neighbourhood of Hove (*The Times*, February 20). The discovery has been made on the downs, north of Hove, where the existence of such remains had not previously been suspected. It is

thought that they may be Roman, possibly of the first century A.D. The discovery was made on February 17 by a Corporation labourer who unearthed a collection of pottery, less than eighteen inches from the surface, when digging sewer trenches on a municipal housing estate. A further find was an earthenware vessel filled with about 450 small bronze coins, on some of which the head of a Roman emperor has been distinguished, but of a date not yet established. It is thought that the settlement, which overlooks Hove from the hills, may have been established about A.D. 50 and have lasted until the third century. The site is being investigated by Mr. H. G. Massey, curator of the Hove Museum, with the assistance of Dr. Cecil Curwen.

Earthquake in Bulgaria

On February 17, an earthquake of considerable intensity was experienced at Gornadjoumaja and Sofia in western Bulgaria. At the same time a strong roaring sound was heard, and many people fled from their homes, though no serious damage or casualties are reported. The epicentre of the shock may have been about fifty miles south of Sofia, where there is the most pronounced seismic centre in Bulgaria. Between the years 1749 and 1936, 1,420 earthquakes had their epicentres in this region, and one at least had an intensity greater than 7 on the Rossi-Fore scale. The most disastrous shocks in Bulgaria in recent years were those of April 14, 17, 18, and 21, 1928, which were felt at Chirpan and Plovdiv and did more than £4,000,000 damage.

Science and Society

THE Division for the Social and International Relations of Science of the British Association is arranging a programme of meetings at which topics of immediate interest and importance will be discussed. The first of these meetings will be held on March 28 at the University of Reading, when two sessions will be devoted to a discussion on "Milk in its Nutritional and Allied Aspects". The chairman of the sessions will be Sir Richard Gregory and Sir Daniel Hall. Other speakers will deal with deficiencies of diet, health aspects, pasteurization, production, cost economic and social implications. It is also proposed to arrange meetings in the early summer in London and Manchester for review of the social relationship of science, and for discussion with special reference to pressing problems in industry and agriculture. In connexion with the Manchester meeting, Prof. H. Levy has been appointed to deliver the Alexander Pedler Memorial Lecture in which he will explain the method of approach in the study of the social problem of science, with particular illustrations of the application of scientific discoveries to industry. During the forthcoming meeting of the British Association in Dundee (August 30-September 6), the Division will hold three sessions when it is proposed to consider the co-ordination of scientific research, population movements and nutrition. Sir Richard Gregory, chairman of the Division, and lately editor of *NATURE*, will deliver an address on "Science and Social Ethics".

Musick Memorial Trophy

THE first award of the Musick Memorial Trophy of the Royal Aeronautical Society has been made to Mr. Arthur Gouge, chief designer of Messrs. Short Brothers, Ltd. The Trophy was founded in 1938 as a memorial to Captain Edwin Musick and his six companions who were lost on January 12, 1938, on the Samoan Clipper, in the South Pacific, during the first commercial flight from U.S.A. to Auckland, New Zealand. It is awarded annually to "the group, body or individual who have made the contribution, development or improvement which by its practical application has become most effective in furthering the safety of aircraft with special regard to trans-oceanic aviation". The award is confined to citizens of the British Commonwealth of Nations and the United States of America. The Trophy, in silver, is valued at £250.

The Night Sky in March

THE date of the spring equinox is March 21^d 12^h U.T. The moon is full on March 5 at 18^h and new on March 21 at 2^h. λ Geminorum (magnitude 3.6) is occulted on March 2, the disappearance taking place as seen from Greenwich at 0^h 23.6^m at position angle 154° from the north point of the moon's disk. $\times$ Canori, a fifth magnitude star, is occulted on March 3 at 18^h 23.4^m; 97 Tauri (mag. 5.1) is also occulted on March 26 at 18^h 43.6^m. Lunar conjunctions with the planets occur as follows: on March 13 with Mars; on March 17 with Venus; on March 22 with Mercury at 11^h and with Saturn at 17^h. Jupiter is in conjunction with the sun on March 6. Neptune is in opposition on March 13. Mercury is at greatest elongation (18° E.) on March 17. Some ten days previously it may be possible to detect this elusive planet in the evening twilight at 18^h nearly due west and at 5° above the horizon. Saturn is an evening star setting at about 20^h in mid-March. Venus, a bright morning star (mag. -3.8 to -3.6), rises before 5^h, preceded by Mars, the rising of which is more than two hours earlier. Under suitable conditions, the Zodiacal Light may be seen after sunset during this month. In the middle of March, Sirius is due south about an hour after sunset. As the sky darkens, the rich assembly of bright stars west of the meridian contrasts with the sparseness of the eastern half of the sky. It is in this less spectacular region, however, that the great space-penetrating telescopes are able to record the remote extra-galactic nebulae, of which notable clusters are in the constellations of Leo and Ursa Major.

Announcements

PROF. HENRY NORRIS RUSSELL, director of the Princeton University Observatory, has been elected *correspondant* of the Section of Astronomy of the Paris Academy of Sciences in succession to the late Prof. E. W. Brown.

MR. W. S. DAVEY has been appointed head of the Chemical Division of the Rubber Research Institute to succeed Dr. E. Rhodes, who has resigned to take up a post under the British Rubber Producers'

Research Association. Mr. Davey is at present senior chemist on the staff of the London Advisory Committee for Rubber Research (Ceylon and Malaya) at the Imperial Institute.

PROF. HELMUTH SCHEEL has been appointed president and Prof. Theodor Vahlen vice-president of the Prussian Academy of Science.

THE third International Congress, under the auspices of the International Union Against Cancer, will be held in Atlantic City, New Jersey, U.S.A., on September 11-16 under the presidency of Prof. F. Carter Wood, director of the Institute of Cancer Research in Columbia University. Further information can be obtained from the Secretary-Treasurer, Dr. Donald S. Childs, 713 E. Genesee Street, Syracuse, New York.

A CONFERENCE on "China in World Affairs and Our Responsibility" is to be held in the Friends House, Euston Road, London, on March 10-11, under the auspices of the China Campaign Committee. The Conference will discuss the present position in China, economic, political and educational reconstruction in China, the rebuilding of universities, etc. Further information can be obtained from the National Organizer, China Campaign Committee, Parliament Mansions, Orchard Street, London, S.W.1.

THE Meteorological Association of the International Union of Geodesy and Geophysics will be held in Washington during September 4-15, under the presidency of Prof. S. Chapman. The subject of Prof. Chapman's address will be "Atmospheric Tides and Associated Phenomena", and the address will be followed by discussion. Other subjects for discussion will include recent developments in aerology and electric and magnetic phenomena of the atmosphere. Further information can be obtained from the General Secretary of the Assembly, Dr. J. A. Fleming, 5241 Broad Branch Road, N.W., Washington, D.C.

THE Zoological Society of London announces that, beginning with this year, its publications will be reorganized. One or more parts of the *Transactions* will appear each year and the *Proceedings* will appear in two series, as follows: (A) general and experimental; (B) systematic and morphological. These can be subscribed for either singly or in any combination. *Proceedings* (C) will no longer be published. In future an "Abstract and Agenda of the Scientific Meetings" will be published, and may be obtained for an annual subscription of six shillings. One volume of (A) and one of (B) will be published annually. Further information can be obtained from the Secretary, Zoological Society of London, Regent's Park, London, N.W.8.

WE regret that the price of Prof. J. D. Bernal's book "The Social Function of Science", noticed in NATURE of February 18, p. 262, was stated incorrectly to be 2s. 6d. net. The price of the volume is 12s. 6d. net.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 337.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Disintegration of Heavy Nuclei

THROUGH the kindness of the authors I have been informed of the content of the letters¹ recently sent to the Editor of NATURE by Prof. Meitner and Dr. Frisch. In the first letter, these authors propose an interpretation of the remarkable findings of Hahn and Strassmann as indication for a new type of disintegration of heavy nuclei, consisting in a fission of the nucleus into two parts of approximately equal masses and charges with release of enormous energy. In the second letter, Dr. Frisch describes experiments in which these parts are directly detected by the very large ionization they produce. Due to the extreme importance of this discovery, I should be glad to add a few comments on the mechanism of the fission process from the point of view of the general ideas, developed in recent years, to account for the main features of the nuclear reactions hitherto observed.

According to these ideas, any nuclear reaction initiated by collisions or radiation involves as an intermediate stage the formation of a compound nucleus in which the excitation energy is distributed among the various degrees of freedom in a way resembling the thermal agitation of a solid or liquid body. The relative probabilities of the different possible courses of the reaction will therefore depend on the facility with which this energy is either released as radiation or converted into a form suited to produce the disintegration of the compound nucleus. In the case of ordinary reactions, in which the disintegration consists in the escape of a single particle, this conversion means the concentration of a large part of the energy on some particle at the surface of the nucleus, and resembles therefore the evaporation of a molecule from a liquid drop. In the case of disintegrations comparable to the division of such a drop into two droplets, it is evidently necessary, however, that the quasi-thermal distribution of energy be largely converted into some special mode of vibration of the compound nucleus involving a considerable deformation of the nuclear surface.

In both cases, the course of the disintegration may thus be said to result from a fluctuation in the statistical distribution of the energy between the various degrees of freedom of the system, the probability of occurrence of which is essentially determined by the amount of energy to be concentrated on the particular type of motion considered and by the 'temperature' corresponding to the nuclear excitation. Since the effective cross-sections for the fission phenomena for neutrons of different velocities seem to be of about the same order of magnitude as the cross-sections for ordinary nuclear reactions, we may therefore conclude that for the heaviest nuclei the deformation energy sufficient for the fission is of

the same order of magnitude as the energy necessary for the escape of a single nuclear particle. For somewhat lighter nuclei, however, where only evaporation-like disintegrations have so far been observed, the former energy should be considerably larger than the binding energy of a particle.

These circumstances find their straightforward explanation in the fact, stressed by Meitner and Frisch, that the mutual repulsion between the electric charges in a nucleus will for highly charged nuclei counteract to a large extent the effect of the short-range forces between the nuclear particles in opposing a deformation of the nucleus. The nuclear problem concerned reminds us indeed in several ways of the question of the stability of a charged liquid drop, and in particular, any deformation of a nucleus, sufficiently large for its fission, may be treated approximately as a classical mechanical problem, since the corresponding amplitude must evidently be large compared with the quantum mechanical zero-point oscillations. Just this condition would in fact seem to provide an understanding of the remarkable stability of heavy nuclei in their normal state or in the states of low excitation, in spite of the large amount of energy which would be liberated by an imaginable division of such nuclei.

The continuation of the experiments on the new type of nuclear disintegrations, and above all the closer examination of the conditions for their occurrence, should certainly yield most valuable information as regards the mechanism of nuclear excitation.

Photoactivation of Solids and its Effect on Adsorption

CONSIDERABLE attention has been given recently to chemical processes involving an activating influence of a crystal excited by irradiation¹. The mechanism of such photosensitized reactions, although unknown in detail, is generally believed to be a more or less complete transfer of the energy absorbed by the crystal to the reacting components, physically or chemically. Accordingly, the essential difference between photosensitized processes and real photochemical ones is the distance between the place of absorption and the place of reaction. But there must also be another, more general, effect of irradiation on the activity of crystals. Due to the change in the electronic state of the particles in the lattice by the absorption of light (change in charge and degree of polarization, formation of space charges, etc.), the forces between the particles are changed and, consequently, there is also a change in potential of the

surface field that determines the chemical activity of the crystal. As in a real crystallographic transition, which causes a difference in the reactivity of the modifications under comparable experimental conditions², so irradiation of an absorbing crystal causes a change of the surface activity that might have a detectable influence on sorption or catalytic processes or on real chemical reactions. Naturally, in many cases, such effects would be expected to be rather small.

In practice, however, there will often be no possibility of deciding experimentally whether a process is photosensitized or activated as just described. But the latter must at least be the case when processes occurring at the surface of a crystal in substrates which do not absorb the irradiation are more or less quenched by irradiating the crystal. Otherwise, this influence of irradiation can scarcely be understood.

Such a phenomenon has been found in adsorption experiments with cadmium sulphide and phenolphthalein. Cadmium sulphide was shaken with an alcoholic solution of phenolphthalein for a given time with or without irradiation with white light, filtered through ferrous ammonium sulphate-quinine solutions. After centrifuging and adding sodium hydroxide the unadsorbed phenolphthalein was measured colorimetrically. The results are shown by the accompanying table.

Percentage phenolphthalein adsorbed (200 mgm. CdS, 20 c.c. solution—60 mgm. phenolphthalein per litre—time of adsorption 30 minutes).

Dark	Irradiated
10.0	1.0
9.2	0.7
8.6	1.2
9.4	1.8

The decrease of the adsorbing power of cadmium sulphide by irradiation is evident. As the residual concentration of phenolphthalein is increased by irradiation, photosensitized bleaching, if it occurs, cannot cause this effect. In the irradiation experiments there has probably been a certain amount of 'dark adsorption' due to unexposed cadmium sulphide particles and to the centrifuging process. It is, therefore, possible that under suitable conditions the adsorption may be totally suppressed by irradiation of the sulphide.

Similar effects have been obtained with a large number of organic dyes, and it has been shown that an exchange of certain groups of a dyestuff molecule has a marked influence on the change of adsorption during irradiation. With the xanthene dye (I), for example, the adsorption decreased from 33 to 23 per cent during irradiation, whilst the adsorption of the dye (II) remained practically unaltered at 54 per cent. It therefore seems possible to use this effect of irradiation on the adsorbing power of solids for separation purposes.

These experiments were performed by A. Aarsaasen and S. Berger. We acknowledge gratefully financial assistance from the fund of the Royal Swedish Nobel Committee.

Mechanism of Magnetization

In a previous note¹ some experimental data were recorded which indicated that one aspect of the classical theory of magnetization is incorrect. For

these experiments a solid-drawn steel tube was used, the thickness of the wall of the tube being 3/16 in., the internal diameter 3/8 in., and the length 24 in.

Further experiments have now been made for which a series of solid-drawn charcoal iron tubes were used as follows. Each tube was of internal diameter 3/8 in. and 24 in. long; the external diameters of the tubes were 9/16 in., 1/2 in. and 7/16 in., respectively, thus giving a thickness of wall of 3/32 in., 1/16 in. and 1/32 in., respectively. The same solenoid was used as for the previous experiments and the results of the tests are shown in the accompanying graph.

The results may be summarized as follows:

- The reduction of the value of H inside the tube becomes greater as the thickness of the wall increases.
- The reduction of H within the tube is a maximum when the tube is magnetized to a condition which about corresponds to the knee of the magnetization curve.
- When the tube is magnetized to a condition

of saturation, the value of H within the tube is practically unaffected by the material of the tube. The results also show that the self-demagnetizing effect of the ends of each tube is negligibly small.

These test data support the view formulated in a previous² note, namely, that the magnetization of a material is initiated at the surface and proceeds inwards by a kind of 'chain effect', so that the flux density near the surface is a maximum and becomes progressively less as the distance from the surface increases.

A comprehensive account of these investigations is now being prepared and will be published shortly.

X-Ray Diffraction by Supercooled Liquid Sulphur

It has been observed that sulphur may be kept, with a little care, in the supercooled liquid state at the ordinary room temperatures (25°–30° C.) in the form of small globules on clean glass surfaces. In some cases it has been possible to keep one and the same globule in the supercooled state for more than three days, even under X-ray exposures. Supercooled liquid sulphur may be prepared also on metal surfaces, for example, brass, aluminium, etc., but in those cases it becomes unstable and solidifies easily, probably due to the crystallizing forces exerted by the metal surfaces. Again, under given physical conditions, the stability is found to be a function of the size or the diameter of the drops. The greater the diameter, the less is the stability. This is probably due to larger surfaces or volumes being more liable to get disturbed. The drops in the supercooled state are found to retain the colour they had at higher temperatures before cooling. Hence it is supposed that the drops maintain exactly the same physical state as they had at the higher temperatures.

X-ray diffraction photographs of supercooled liquid drops have been taken by the transmission method. Taking the factors of high absorption by sulphur of the copper $K\alpha$ radiation used in the experiment and also the stability of the supercooled drops into consideration, small globules (0.3–0.5 mm. in diameter) of liquid were prepared on an extremely thin glass film. One of the globules was then placed before the slit (0.4 mm.) being mounted on the carrier of a special collimating system¹. The pattern obtained with yellow drops supercooled from a temperature just above the melting point of sulphur is reproduced

X-RAY DIFFRACTION PHOTOGRAPH OF SUPERCOOLED SULPHUR.

herewith. The single band recorded in the photograph corresponds to a Bragg-spacing which agrees well with those observed by Blatchford² and by Das¹ in the case of liquid sulphur maintained at higher temperatures above the melting point. The accompanying table brings together all the results.

BRAGG-SPACING OF LIQUID SULPHUR.

Author	Temperature	Spacing ($\times 10^8$ cm.)
Blatchford ²	130° C.	3.68 $\pm$ 0.01
Das ¹	128° C.	3.76 $\pm$ 0.02*
Das and Das Gupta	27° C. (supercooled)	3.68 $\pm$ 0.02

* This new value of the spacing is yet unpublished. According to Das, it is more accurate than that reported by him previously¹ and than that of Blatchford².

It is interesting to note that the spacing at 128° C. is larger than that at 27° C. This is evidently due to the thermal expansion of the liquid with rise of temperature.

The study of a liquid in the supercooled state by X-ray diffraction has not, hitherto, been reported. The results of further investigations, now in progress, by X-ray and other methods will be published elsewhere; they may be expected to throw much light on the supercooled liquid state, of matter in relation to the ordinary liquid and the solid states.

Structure of the SnCl_4 -- Group

In a letter in NATURE¹, Cox, Shorter and Wardlaw examined the stereochemistry of bivalent tin and lead and arrived at conclusions which are not in agreement with some of our results.

The compound $\text{K}_2\text{SnCl}_6 \cdot 2\text{H}_2\text{O}$, which is described as being orthorhombic with $a = 12.02$, $b = 9.11$ and $c = 8.23$ Å., and the space-group *Prima*, has been studied quite recently in our laboratories and the results so far obtained, although they lead to the same unit cell and space-group, do not suggest that the SnCl_4 -- group is co-planar.

The actual formula of potassium chlorostannite is worth consideration. Rammelsberg² and others^{3,4} found only one water molecule of hydration, while Richardson⁵ later obtained two water molecules. A thorough study of the dehydration of hydrated potassium chlorostannite gave strong evidence for the existence of only one water molecule in the compound, in agreement with Rammelsberg's results. Moreover, the calculation of the number of molecules contained in the unit cell (density⁶, 2.514) leads to 3.88 of $\text{K}_2\text{SnCl}_6 \cdot \text{H}_2\text{O}$ and to only 3.68 of $\text{K}_2\text{SnCl}_6 \cdot 2\text{H}_2\text{O}$, the difference between this number and 4 being due partly to the over-evaluated amount of water.

A Fourier-Patterson-Harker and a Fourier-Bragg diagram suggested a structure which is almost identical with that found by MacGillivray, de Wilde and Bijvoet⁷ for $\text{K}_2\text{HgCl}_6 \cdot \text{H}_2\text{O}$. Thus the SnCl_4 -- groups are obtained from octahedral SnCl_6 groups sharing edges parallel to the (010) plane and forming columns of so-called 'rutile octahedra' in the direction of the b axis.

In conclusion, may we suggest that the a , b , c axes, as chosen by Cox, Shorter and Wardlaw, be called b , c and a , in accordance with the usual convention.

Direct Perception of Pigment in the Nerve Tissue of Human Retina

DURING spectroscopic study of a flavoprotein compound in heart muscle preparation, it was noticed that two diffuse absorption bands of the pigment remained always perceptible, however dilute was the preparation or thin the layer examined. Further observations have revealed that these two bands remain perceptible even in the absence of muscle preparations. Moreover, examination with a small dispersion spectroscope of any source of artificial light shows the presence of two diffuse absorption bands lying at about 495 m μ and 455 m μ . The first band is more distinctly visible at a lower intensity of light, while the second band can be more easily perceived when the light passes through a suitable filter such as a solution of ammoniacal copper sulphate or Wratten filter D.

In order to see these bands, it is essential to use a very low dispersion spectroscope such as a micro-spectroscope ocular attached to a microscope or a prism pocket spectroscope and a source of light giving a continuous spectrum. The relative intensities and positions of these bands remain constant and are independent of either the optical system or the source of light. This clearly indicates that the absorption bands are not due to the instruments but to a substance present in the observer's eye and lying on the path of rays from the light source to the sensitive portion of the retina. As the cornea, lens, aqueous and vitreous fluids are devoid of any perceptible colouring matter, the pigment responsible for the absorption bands must be present in the retina itself, in the nerve tissue lying in front of the visual cells (cones) and most probably in the *macula lutea* and *fovea centralis*.

The presence of this pigment in the retina can also be deduced from an examination of the visibility data obtained in the 'step-by-step' matching of the intensities of two adjacent spectral regions. In every case these data, whether for normal^{1,2} or for the colour-blind³ eye, reveal two distinct depressions in the visibility curve. These two depressions, ascribed⁴ to a pigment present probably in the optical path of the eye, lie at about 495 m μ and 455 m μ , occupying therefore the same positions as the absorption bands described above.

As to the nature of this pigment, we can suggest only that it may be either a flavin or a carotinoid compound, or possibly a mixture of both and present in the thin layer of nerve tissue of the macula in a concentration sufficiently high to give a perceptible

absorption spectrum. In fact, flavin and its derivatives⁵ as well as β -carotene⁶ have been obtained from ox retina. Both pigments have somewhat similar absorption in the region of the spectrum occupied by the above bands. However, the exact nature of the substance responsible for the perception of these two absorption bands will only be solved by a careful study of the pigments obtained directly from the *macula lutea* of the human eye.

The two absorption bands described above represent, so far, the only slight discontinuities which the eye can perceive in the otherwise continuous spectrum of an artificial source of light. They denote only a very slight imperfection in the eye caused by the presence of pigments in the nerve tissue of the retina itself, an imperfection which is highly magnified by the use of a small dispersion spectroscope.

This observation also serves as warning against the use of the direct method of spectroscopic examination in the general survey of flavin or carotene distribution in different tissues and their extracts. In fact, if this method is used, it will not be possible to detect any cells completely devoid of these pigments.

Differentiation of Disaccharide-splitting Enzymes

WEIDENHAGEN's theory of the specificity of glucosidases and disaccharases¹, as opposed to the theory of specificity of Leibowitz², depends largely upon the claim that the maltose-splitting factor of taka-diastase is an alpha-glucosidase identical with the sucrose-splitting factor (glucosucrase). According to Leibowitz, on the other hand, taka-maltase is a specific glucomaltase, inert to alpha-methyl-glucoside and distinct from the taka-sucrase.

Recently³ we reported the possibility of freeing taka-maltase from accidentally accompanying alpha-methyl-glucoside splitting enzyme on the basis of the thermostability of the former. It has now been found that on brief incubation at pH 8.5 the heat-stable taka-maltase retains full activity whilst taka-sucrase is completely destroyed. Hence it follows that taka-maltase and taka-sucrase are two distinct enzymes. Consequently, the theory of Weidenhagen, against which serious objections have already been raised, may now be considered refuted.

Reduction of Heart Flavoprotein

WE recently described¹ the catalytic properties of a flavoprotein isolated from heart. At that time we were unable to observe the reduction of flavoprotein by reduced coenzyme I. We now find that, by eliminating coloured impurities in the various components of the catalytic system, the rapid reduction of flavoprotein to its leuco form can be readily demonstrated. Under the conditions of our experiment, the leuco form is non-autoxidisable but can be oxidized by 'carriers' such as methylene blue. The mechanism of the catalytic effect of heart flavoprotein involves a cycle of reduction by reduced coenzyme I and oxidation of the leuco form by some suitable 'carrier'.

Relative Sexuality in Unicellular Algae

IN a series of papers, Dr. Franz Moewus, working first at the Kaiser Wilhelm Institut für Biologie in Berlin, and later at Erlangen and Heidelberg, has published a number of very remarkable results on relative sexuality in unicellular algae. The qualitative results are in agreement with those of other workers of the same school. We wish, however, to direct attention to a feature of his quantitative data which casts grave doubt on their reliability.

Moewus' last paper¹ described the genetical behaviour of various races of *Chlamydomonas eugametos*. The xygotes derived from crosses within dioecious races, that is, races with genotypical sex-determination, are said to give 3.08 per cent exceptional gametes. Clones grown from these exceptional gametes can produce gametes of both sexes, that is, they show phenotypical sex-determination. These abnormal segregations are ascribed to crossing over between the two non-allelomorphic sex determiners. In each of the crosses 1-9, 18-24, and 37-40 he tested 500, or occasionally 400 or 300 xygotes. In 27 of the 31 crosses, 500 xygotes were tested, and the number of exceptions was between 13 and 17 in every case.

Struck by this astonishing consistency, we applied Pearson's χ^2 test to all 31 crosses, and found $\chi^2 = 2.423$ for thirty degrees of freedom. The probability of obtaining as bad or worse a fit by sampling is $P = 1 - 4.7 \times 10^{-13}$. That is to say, only once in about 10^{11} trials would so good a fit be obtained by chance. In the same paper (Table 7) Moewus once more calculates the above "cross-over" value from four samples of 5,000 xygotes each, by observing the number of cells dying as a result of meiosis. The numbers are 152, 158, 151, and 155, forming exactly 3.08 per cent of the total, as before. We can therefore add the total value of χ^2 obtained from them, namely, 0.201 for four more degrees of freedom, to the former value, obtaining a grand total of $\chi^2 = 2.624$ for thirty-four degrees. This gives $P = 1 - 6.6 \times 10^{-14}$.

A second suggested cross-over frequency between the male determiner *M* and the gene *t* for *Subheterocis* amounting to 9.8 per cent is deduced from six crosses (numbers 26-39 and 42-43). Here $\chi^2 = 0.0410$

for five degrees of freedom. So $P = 1 - 6.3 \times 10^{-4}$ approximately, though even Sheppard's table of the probability integral is not accurate enough to give the second significant figure with certainty.

Nor is the truly remarkable agreement between theory and observation confined to the paper in question. In a paper² on *Protosiphon botryoides*, Tables 2, 3, and 4 record twenty-two experiments in which the cultures segregated into approximately equal numbers. Either the two halves gave different kinds of gamete or one gave gametes and the other did not. In eleven experiments where thirty cultures were counted, the deviation from equality never exceeded 17 and 13. In eleven experiments where ten cultures were counted, the largest deviation is 6 and 4. For twenty-two degrees of freedom $\chi^2 = 5.06$, $P = 1 - 6.9 \times 10^{-1}$.

So good a general agreement with theory would be obtained by chance once in 3.5×10^{11} trials; that is to say, if every member of the human race conducted a set of experiments of this type daily, they might reasonably hope for such a success once in fifty thousand million years. There are two alternatives to the hypothesis of chance. One is that a wholly new type of biological regulation has been unwittingly discovered, by which the frequency of segregation is controlled with extreme sharpness, and that this applies to three segregations in two species. The other is that the author has consciously or unconsciously adjusted his observations to fit his theory. As this work is of fundamental importance for the theory of sex-determination, it is desirable that these experiments should be repeated by an independent observer. Until this is done, those parts of Dr. Moewus' genetical theory which are based on these numbers cannot, we think, be accepted.

Embryology of the Symphyla

OWING to the significance which is attached to the Symphyla in speculations on the origin of insects, a knowledge of their embryology has become desirable. Having recently obtained, in large quantity, the eggs of a local species of *Hansenella*, I have been able to work out a fairly complete story of the development of these remarkable animals. A detailed account of this will be published later; the present note records a few points which are significant on phylogenetic grounds.

Cleavage is total, as in Collembola and some Diplopoda. By tangential division of the large yolk pyramids, an outer layer of small cells and an inner layer of very large cells arises, both rich in yolk. From the former arises the blastoderm. From the latter arises by further division the internal mass of yolk-cells. These are not pure vitellophages, however, for from them develop the fat-body and mid-gut epithelium.

An embryonic area forms by ventral thickening of the blastoderm. A precocious flexure then forms in the embryonic area, as in some diplopods, and thereby the germ-band becomes defined. A 'dorsal organ' is present; but there are no embryonic membranes.

The mesoderm arises by bilateral separation of cells from the germ-band. Segmentation of the mesoderm into somites synchronizes roughly with external segmentation of the germ-band. In the head there is no external sign of segmentation. The labial segment arises as part of the abdomen. Behind it are formed seven leg-bearing segments, followed by a pre-anal segment, the appendages of which are the cerci. On the anal segment appendages are vestigial.

In the head, six pairs of coelomic cavities form; each abdominal segment is furnished with a single pair of coelomic sacs. The antennary and pre-antennary coelomic sacs co-operate to form the aorta. The coelomic sacs, from the mandibular backwards, grow through the yolk-cells, enclosing part of these as mid-gut epithelium; they all furnish cardioblasts for the heart. The pre-mandibular coelomic sac undergoes a remarkable development, for from it arises a large excretory gland which degenerates at the time of eclosion; in association with it is a clump of nephrocytes, probably homologous with the sub-oesophageal bodies of insects. The salivary gland is a remnant of the maxillary coelomic sac.

Great significance is naturally attached to the reproductive organs. The genital tubes arise by concrescence of the vestiges of the coelomic sacs from the fourth abdominal to pre-anal segments. Vestigial coelomoducts survive in the pre-anal segment until after eclosion, the larva presenting the appearance of a potentially opisthognate rather than prognate myriapod.

The most noteworthy feature of the nervous system is the development of its ganglia in association with 'ventral organs' as in *Peripatus*. The 'ventral organs' retrogress; from the remnants arise the eversible sacs.

The Symphyla appear to be the survivors of a very ancient stock of myriapods, closely related to the opisthognate forms from which the insects were derived, but already distinguished by the acquisition of a secondary anterior genital opening, which the diplopods have inherited from them.

Studies on *Chironomus* Chromosomes with the Polarizing Microscope

In previous communications¹ it was pointed out that in protoplasm there are linear units forming either a brush heap of fibrils or having a symmetrical arrangement of them oriented end-on-end in parallel rows. Furthermore, it has been shown² that, during the appearance of mitotic spindle fibrils, living matter possesses a continuity in structure which only fibrous units can adequately impart to it. In D. M. Wrinch's model³, a chromosome has been pictured as consisting of a net of polypeptide molecules in parallel forming the warp of the fabric, and of nucleic acid molecules constituting the woof. In my opinion, Wrinch's assumption of fibrillar units offers several possibilities, especially in regard to the postulates of genetics and to the findings of the cytologists as to the capacity of the chromosomes to swell, to contract, to grow, and to divide. On the other hand, it is known⁴ that fibrils of nucleic acid are optically negative and run parallel with the axis of sperm heads.

It is the purpose of this note to indicate the essential features of a chromosome model of polypeptide chains in parallel with nucleic acid molecules. Salivary glands of a *Chironomus* sp. were selected from female larvae preparing to pupate. Slight pressure on the salivary gland nuclei not only separates the chromosomes from each other but also reveals most strikingly, at the same time, the chromomeric, banded nature of the heterochromatin⁵. It is true, H. Bauer in 1935 failed to find anisotropy in chromosomes of salivary glands even in a stretched state; but H. Ullrich in 1936 emphasized the fact that the chromomeric bands are doubly refractive after injury. When the chromosomes are pressed out into a favourable medium, for example, paraffin oil, the double-refraction of the transverse bands is, though often weak, nearly always capable of verification. Furthermore, it becomes pronounced when the chromosomes are intensively extended between two micro-needles as used by P. Vonwiller and A. Audova. After cessation of stretching, the chromosomes contract without attaining their initial length.

It has occurred to me that these contractions may be due to the shortening of protein fibrils by molecular folding or helical contraction as postulated by W. T. Astbury⁶ for wool and hair. Along with the lengthening, the chromosome becomes less transparent in the interchromomeric bands, and the anisotropy measured in I-values often increases considerably. But the extended chromosomes are always negatively birefringent with respect to their long axis. So I see no reason for the assumption of a cross-arrangement of nucleic acid molecules, but I assume the same direction of both the polypeptide chains and the nucleic acid molecules. The nucleic acid bands may form zones of alternating density along the micelle⁷. With regard to the chromosome micelle, my agreement with Wrinch consists in the assumption of a contractility and of swelling properties in comparison with which those of the coarse animal fibrils vanish into insignificance.

Our knowledge of the molecular structure of the chromosome micelles is slight compared with the knowledge of the structure of materials like cellulose or other derivatives of protoplasm. Further work is now in progress on some points raised by these experiments, and will be reported in due course.

Food of Salmon Parr

AN investigation of the stomach contents of salmon parr from the River Dee and its tributaries has been in process during the past twelve months, and, in view of the scarcity of published data on this subject, a preliminary note may be of general interest.

The feeding is totally indiscriminate, and a single meal may include representatives of a dozen or more species of animals taken at random from under stones (insect-larvæ), free water (Cladocera and small beetles), or surface-driftage (aerial and terrestrial arthropods), while the large number of dipteran flies (especially Empididæ and Mycetophilidæ), uniform in species, sometimes found within a single stomach suggests that the fish may have snapped at swarms in the air itself.

Until so late as the end of October, food organisms of sub-aerial origin are more numerous than aquatic types in the stomachs, and the numerical abundance of Hemipteran plant pests, especially those associated with the alder (some species of *Psylla* and of *Cicadina*), points clearly to the desirability of encouraging the growth of trees and shrubs along the banks of the streams, especially where the benthic fauna is poor.

Details of the full seasonal cycle and a list of food organisms will be published later.

Ancient Egyptian Astronomy

WITH reference to Dr. O. Neugebauer's letter in *NATURE* of January 21, p. 116, on this subject, may I express concurrence in respect to the neglect of this matter? Whereas excellent work has been done by Dareese, Schott, Gundel and Zinner on the Continent and by A. Pogo in America, very little attention is being given to it in England.

The Stobart tables, to which Dr. Neugebauer refers, can, however, never be quite forgotten, since it was by them that Brugsch definitely identified the planets in the astronomical ceilings of the temples of Denderah and Edfu (Roman period), the two temples of Esneh (Ptolemaic period), the temple of Medinet Habu, the Ramesseum and the tomb of Seti I (New Kingdom). Similar identifications of the planets have since been made on the Karnak clepsydra (Amenophis III) and on the Senmut ceiling (Hatshepsut, say, 1500 B.C.) and by Dareese on a Tenth Dynasty coffin from Asiut (say, 2000 B.C.). Venus may perhaps be referred to in the Fifth and Sixth Dynasty Pyramid texts (say, 2500 B.C.). Recently I noticed the planets in the coffin of Heru-neteh-tef-ef in the British Museum (about 350 B.C.).

The standard "schemata coeli" appears to have been developed about the beginning of the New Kingdom (say, 1600 B.C.) and consists normally of three registers, containing (1) the 36 dekans, Sirius, the superior planets, the "meta-dekans" and the inferior planets; (2) the northern stars; (3) the twelve monthly feasts.

In the preceding Middle Kingdom (say, 2000 B.C.), the scheme is simply one of four figures: the Goddess of Heaven, the Great Bear (Ox-leg), Sirius and Orion.

The Pyramid texts contain numerous references to Sirius and Orion.

Pogo¹ has studied the tables of dekanal stars and hours on the Asiut Tenth Dynasty coffins, and it is

clear that, at that era, the Egyptian notions of time were most vague, and similarly the Eighteenth Dynasty Karnak clepsydra is by no means accurate. Even the table of dekans was never standardized, but differs from dynasty to dynasty.

It seems very doubtful if one can safely attribute much mathematical ability to the ancient Egyptians on the basis of the demotic texts to which Dr. Neugebauer refers. From the time of the foundation of the Museum at Alexandria, Greek methods appear to have been adopted. The Denderah planisphere shows that the essential features of purely Greek astrology had been incorporated into the Egyptian system in Roman times, and even the "ancients" (Petosiris and Nechepeo), so frequently alluded to by classical writers, seem to have acquired many notions from the Greeks, if one may judge by the fragments of their lore contained in the writings of Firmicus.

For those who are interested, I may remark that the replica of the Karnak clepsydra in the Science Museum at South Kensington shows most of the features of the standard figure of heaven, and agrees in most respects with the oldest existing example, that from the ceiling of the tomb of Senmut.

Finance for Scientific Research

I SHOULD like to comment on the leading article in *NATURE* of January 28 on this subject.

I think that the best hope lies in approaching this matter in a truly scientific spirit, when the authorities, it is to be hoped, would not feel in duty bound to defend the present position nor would reformers require to attack it. Research associations were originally formed, with Government help, to introduce research into various industries, and there was a belief that the advantages of research to the industries would become so apparent that after a period industries would provide all the funds for research themselves.

In general, the industries have become convinced of the advantages of research, but their prosperity and hence their ability to finance research has been impaired by circumstances affecting their supplies of raw material and their markets at home and abroad, which have been beyond the influence of the research associations.

Research associations are supposed to confine themselves to research on the processes of their members and leave these other matters alone. In my experience, this limitation cuts off a most important field of research, and tends to preclude any large advance of economic importance. In many cases, certainly in textiles, a large part of the price of the finished article consists of the price paid for the raw material. Unless and until attention is paid to ensuring ample supplies of uniform quality and reasonable price, no amount of research upon processes will overcome the difficulties of British industry.

Again, a research association cannot undertake research to develop entirely new uses for its raw material outside existing channels, because it is working for members who are operating established

processes. It seems to me that many notable advances depend on using some raw material in a new way, such as using rubber for tyres instead of rubbing out pencil marks. By neglecting to finance this kind of research, are we not leaving the most fruitful field without fertilizer?

From the financial point of view, the main expenditure on research is on the salaries and wages of the research workers. At present, there are glaring irregularities owing to differences in organization and finance. Scientific workers in universities are in permanent positions; but they are paid for their educational services rather than for research. Scientific workers in the many Government establishments are in permanent establishments and are paid upon recognized salary scales to do research. Scientific workers in the employ of private firms are likely to have a permanent career and prospects if the firm is sufficiently stable, and they may be paid to some extent by results. At present, the position of scientific workers in research associations is the least satisfactory. The continuance of their employment is only reasonably assured over the quinquennial period for which Government grants are arranged. My experience, which may be usual, is that young people

join the staff to gain valuable experience of industrial research, and seek an assured career in a Government research station, where a better salary and prospects are open to them, or they leave to enter private employment in industry.

This means that co-operative research undertaken by an industry and partly paid for by the industry is at a disadvantage in retaining an experienced staff, compared with an industry, which for some reason or other pays nothing towards co-operative research, either getting it done by a Government establishment or relying on individual and private effort. This is neither just nor advisable. Co-ordination of research effort all along the line is necessary, and research workers should choose their field because they are attracted to it, not because it offers the best opportunities of a career.

Points from Foregoing Letters

PROF. N. BOHR, discussing the recent observations on the break up of certain heavy nuclei when bombarded with neutrons into particles of approximately equal size, suggests that this effect might be treated approximately as a classical mechanical problem, on the assumption that the excitation energy is distributed among the various degrees of freedom in a way resembling the thermal agitation of a solid or liquid body. The usual radioactive phenomena would then be analogous to the evaporation of a molecule from a liquid drop.

Experiments reported by Prof. J. A. Hedvall and Dr. G. Cohn indicate that the adsorption of phenolphthalein (in alcoholic solution) by cadmium sulphide, is reduced when the latter is activated by irradiation with white light. A similar effect has been obtained with various organic dyes.

Further experiments by Dr. T. F. Wall show that in iron tubes the reduction in the value of H inside the tube becomes greater as the thickness of the wall increases, and is a maximum when the tube is magnetized to a condition which about corresponds to the knee of the magnetization curve. This, he states, supports the views previously formulated that one aspect of the classical theory of magnetization is incorrect, and that the magnetization of a material is initiated at the surface and is transmitted inwards by a kind of 'chain effect'.

An X-ray diffraction photograph of a drop of supercooled liquid sulphur at $25-30^\circ\text{C}$. is submitted by S. R. Das and K. Das Gupta, who point out that the study of supercooled liquids by X-rays has not hitherto been reported.

X-ray studies of potassium chloroplatinate crystals lead H. Brasseur and A. de Rassenfossé to the view that the SnCl_4^- group is not co-planar. In other

respects (that is, size of unit cell and space-group), their findings agree with those of Cox, Shorter and Wardlaw.

By examining with a very low dispersion spectro-scope any source of artificial light giving a continuous spectrum, it is possible, according to Prof. D. Keilin and Dr. E. L. Smith, to observe two diffuse absorption bands at about 495 and 455 m μ . These, they state, are due to a pigment in the retina which may be either a flavin or a carotinoid compound, or possibly a mixture of both.

At pH 3.5, taka-maltase is stable, but taka-sucrase is quickly destroyed. Hence, according to Dr. J. Leibowitz and S. Hestrin, these two are distinct enzymes.

Discussing results obtained by Dr. T. Moewus in his genetical experiments with unicellular algae, U. Philip and Prof. J. B. S. Haldane find that the probability of their occurrence is so low that one must assume that either a new type of biological regulation is involved or that the author has consciously or unconsciously adjusted his observations to fit his theory.

Dr. O. W. Tiegs describes the development of the embryo of the Australian arthropod *Hanseniella*. It indicates that the Symphyla, the insect class to which it belongs, are survivors of a very ancient stock of myriapods distinguished by the acquisition of a secondary anterior genital opening.

From observations of the chromosomes of salivary gland nuclei of *Chironomus*, pressed out into paraffin oil, Dr. H. H. Pfeiffer concludes that they show definite double refraction of the transverse bands, particularly when stretched. The author considers that Dr. Wrinch's model of net-structure offers interesting possibilities of explaining the contractile and swelling properties of the chromosomes.

Research Items

Early Bronze Age in Wessex

MR. STUART PIGGOTT has examined evidence belonging to the final phase of the Early Bronze Age culture of Wessex with the view of establishing the existence of a culture corresponding chronologically with the food-vessel phase of northern England, and intervening, in a ceramic sense, between the beaker and omerary urn, and forming a final phase in the Early Bronze Age (*Proc. Prehist. Soc.*, N.S., 4, 1; 1938). Such a phase had been postulated in the typological series of bronze implements, while for a great many years a remarkable series of grave groups has been known, incorporating elements (often spectacular in their implication of material wealth), which are peculiar to the area. Obviously they throw a great deal of light on trade relations both internal and overseas. Analysis of the archaeological evidence points to an intrusive culture with types divisible into two groups, those of a southern (maritime) origin and those whose affinities suggest early entry overland from the north. In the first category are bronze daggers with mid ribs and/or lateral grooves, certain pottery forms, notably incense cups, beads of blue faience, now established as of Egyptian origin; and in the second group gold ornaments of Irish origin, and beads and pendants, stone battle-axes of the Snowhill type, pins of Germanic type, and perhaps flanged axes. With the two groups are certain exceptional objects. We are thus faced at the end of the beaker phase with the sudden flowering of a true bronze age, marked by an opening up of trade connexions all over Europe, and the appearance of new types of weapons, tools and ornaments, and a radical change in burial rites. Such a change cannot have taken place without external stimulus, so radical that it cannot have been brought about except by actual settlement—a wave of prehistoric migration from Brittany, a dominant and intrusive aristocracy, who lorded it over a basic folk-culture of food-vessel type, which, however, ultimately absorbed it.

Secret Societies of Sierra Leone

A PRELIMINARY report on the expedition of the University Museum, Philadelphia, to West Africa in 1937 ("The Sherbro of Sierra Leone" by H. U. Hall. Pp. 52 with map. Philadelphia: The University Press, 1938) includes among other matters a description of the place and function of the various secret societies among the Sherbro, or Bolom, of Sherbro Island and the chiefdom of Shenge (Kagboro), in which the old Sherbro culture is best preserved. The population of the island is estimated at 15,571, this figure including 1100 Mendi; while Shenge chiefdom is estimated to have a population of about 15,200. Sherbro Island consists of two chiefdoms, over each of which is a paramount chief, chosen from ruling 'houses' or *rams*, exogamous units composed of blood-relations, in some of which patrilineal descent now prevails. The matter of succession by descent figures not only in regard to rulership, but also in the matter of the organization of the more important secret societies, one of which, *Poro*, was formerly a powerful instrument of government. Secret societies still play a very significant part in

Sherbro life. A man who does not belong to *Poro*, or the third society intrusive *Thoma*, has no standing in the community. Membership of the women's society, *Bundu*, is also obligatory for women. *Poro* is exclusively for men, but *Thoma* is a mixed society, as is also the *Niandung* society among the people of the Ndama chiefdom. *Poro* is now 'put in the bush' about once in three or four years, the bush being a grove of large cotton trees, which, though not enclosed, is strictly barred to women and non-members. When *Poro* is in session the *Poro* "devil eats" the candidates, who are seized *pro forma* if willing, and violently if not willing. This is a ceremonial death through which the candidate enters the world of the spirits of the ancestors. Emergence from the bush at the end of the period of initiation is the equivalent of resurrection, or rather a new birth, brought about by "beating the devil's belly" until he vomits the candidates he has swallowed. In former times decisions affecting the affairs of a chiefdom, both internally and in relation to other chiefdoms, were all taken in the *Poro* council.

Distribution of Vitamins A₁ and A₂

G. WALD (*J. Gen. Physiol.*, 22, 391; 1938) has examined the distribution of vitamins A₁ and A₂ in the eye tissues and livers of freshwater and marine fishes by means of the antimony chloride reaction, which yields with A₁ a band at 615–620 mμ and with A₂ a band at about 696 mμ. In the retina the presence of vitamin A₁ is diagnostic of the operation of a rhodopsin and vitamin A₂ of a porphyropsin cycle. The eye tissues of all permanently marine fishes examined except the tautog contained vitamin A₁ alone, while those of all permanently freshwater fishes possessed only vitamin A₂. Those of all potentially migratory fishes, except perhaps the alewife, contained mixtures of both A₁ and A₂. Most livers contained mixtures of both vitamins A₁ and A₂, and occasionally in proportion the reverse of those in the eye tissues.

Nutritional Cytopenia in the Monkey

W. C. Langston, W. J. Darby, O. F. Shukers and P. L. Day (*J. Exp. Med.*, 68, 923; 1938) fed young rhesus monkeys (*Macaca mulatta*) on a diet containing casein, polished rice, whole wheat, salt mixture, sodium chloride, cod liver oil and ascorbic acid, with the result that they developed a syndrome characterized by anaemia, leukopenia and loss of weight. Ulceration of the gums and diarrhoea were common, and death took place between the twenty-sixth and hundredth day. Four animals were given the deficient diet with the addition of 1 mgm. of riboflavin daily and developed the characteristic signs and died in periods of time similar to the survival of the other monkeys. Nicotinic acid alone or combined with riboflavin and thiamin chloride also failed to alter the course of the deficiency. On the other hand, when the deficient diet was supplemented with either 10 gm. of dried brewers' yeast or 2 gm. of liver extract daily, normal development took place, and there was a normal blood picture for a long period. It is obvious, therefore, that yeast and liver

extract contain a substance, for which the authors propose the term 'vitamin M', which is essential to the nutrition of the monkey, and is not identical with any of the factors of the vitamin B complex which have been chemically identified.

Action of Eserine on Pancreatic Secretion

L. LIAOI (*Biochim. et exp. experiment.*, 25, 445; 1938) carried out experiments on dogs to determine the action of eserine on the external secretion of the pancreas. He found that small doses of this drug ranging from 0.10 mgm. to 0.18 mgm. per kilo injected intravenously had a stimulating action on this secretion as the result of two different mechanisms. The first acted through the vagus, while the second was connected with an increase of the stimulus produced by secretin, which in turn had been increased in quantity by the action of eserine. On the other hand, larger doses of eserine led to a diminution of the secretion and larger doses still might arrest the secretion altogether if it had started spontaneously. Liaoi also found that pancreatic juice secreted after the administration of eserine was capable of digesting coagulated albumin without having received any previous activation.

Colonization of Krakatau by Mammals

In 1883, the great eruption of Krakatau destroyed all vegetation and covered the island with a layer of hot ashes several metres deep. It may be assumed, therefore, that, whatever mammals existed previously, none survived the eruption. In an interesting account of the mammals now present on the island, Dr. K. W. Dammerman indicates the stages of the colonization (*Troubia*, 16, 421; 1938). In 1908, Jacobson collected no mammals and saw none, probably none had yet arrived; but by 1919 bats, *Cynopterus brachyotis*, were present on two islands of the group; in 1920 a second species of the same genus was found on Krakatau itself, although on Verlaten Is. it did not appear for ten more years. It is noteworthy that these two species are fruit-eaters and that insectivorous bats were first collected in 1928 (*Hipposideros diadema*); in 1933 a fourth bat species made its appearance. The only other mammals which have so far gained a footing on the islands are rats. There was none in 1917, but by 1919 when a settler had been present for two years, the house-rat (*Rattus r. diardi*) had become a nuisance. By 1924, when the settler had gone and his house had already become a ruin, the rats had gone. This may have been due to the increase of the large python, but that is unlikely because by 1933 rats were again numerous. A second rat (*R. r. jalorensis*), the widespread Malay country-rat, had become established and was plentiful in 1928. The author notes that on his visits in 1933 and 1934 he saw a small and emaciated black dog, which must have escaped from some landing party and had been able to eke out a poor existence.

Migrations of the Gannet

The origins of British gannets are few so that the movements of ringed birds are more easily related to breeding places. Of 6,384 gannets ringed, 203 have been recovered (3.2 per cent) and the recoveries, as analysed by Dr. A. Landsborough Thomson, show that birds in their first year are the most extensive wanderers (*British Birds*, 32, 282; 1939). Indeed more young birds are captured in African waters than in

European. Older birds tend to confine their winter wanderings to the western shores of France and Spain, but it is clear that in general the approach of autumn brings with it a southward movement, which by the end of December has carried at any rate the birds of the year beyond the southern limits of Europe. A few scattered records show that occasionally gannets born on the west coast of Britain find their way in later years to the North Sea and even to the Baltic, and one Bass Rock individual was recovered from the Faeroes, near another breeding station. The oldest gannet recovered had reached an age of nine years, and it was then within a few miles of Ailsa Craig, where it had been ringed as a nestling.

Names of British Fishes

SCIENTIFIC names of even common British animals are still in the melting pot of priority; but a useful effort to establish the nomenclature of ten families of British fishes has been made by A. Fraser-Brunner (*Ann. Mag. Nat. Hist.*, Ser. 8, 2, 410; Nov. 1938). The changes indicated mainly concern generic and subgeneric names, and for the larger families keys to the characters of these groups are given. Two new generic names are used: *Eutrigla* for *E. gurnardus*, which seems to be confined to European waters and is the only member of the genus; and *Diplecogaster* to include three of the gobies, the former *Cyclopterus bimaoulatus*, selected as the type of the new genus, *Lepidogaster microcephalus* and *L. pellegrini*. The list includes two species which have recently been added to the British list—*Syngnathus rostellatus* from the Thames estuary and *Ammodytes marinus* recently described by Raitt.

Size of Nucleus in *Ricinus communis*

In a communication to the Editors, Flora M. Scott, of the University of California at Los Angeles, comments on the very large size of the nuclei in *Ricinus communis*. Nuclei of the apical meristem, 3–4 microns in diameter, measure approximately 38 cubic microns in volume; nuclei of the differentiated pith and cortex, 332 cubic microns. This eight-fold increase has been shown by Monschau (*Protoplasma*, 9, 536; 1930) to be a fairly general condition. In differentiating spiral elements, however, the diameters, or major axes of the larger nuclei range from 30 to 60 microns, so that resultant volumes may reach 50,000–60,000 cubic microns in round figures, an increase approximately 1,500-fold. When volume is plotted against frequency (some 1,800 nuclei were measured) a many-peaked graph is obtained. The earlier maxima occur at 332, 585, 755, 845, 1,146, 1,860 cubic microns, that is, at intervals of approximately 200 cubic microns. Thereafter the peaks occur with somewhat less regularity, and the curve flattens as it passes to 18,000, 22,000, 33,000, 55,000 and 60,000 in round figures. Since the diameters of the largest nuclei never exceed values approximately half the diameters of the containing vessels, nuclear diameter appears to be dependent on vessel diameter. Increase in volume is shown not to be attributable to chromatin. Dehydration of living nuclei by means of absolute alcohol indicates a relatively higher content of free (that is, removable) water in the largest nuclei, but the residual volumes after such dehydration show an actual volume increase over the meristem nucleus, 8 to 250-fold. This material is therefore mainly karyolymph. A detailed account will be published shortly.

A Dwarf Mutation in Coffee

IN an investigation of the genetics of the coffee plant, *Coffea arabica*, C. A. Krug, of the Instituto Agronomico of São Paulo, Brazil, has studied a dwarf type which appears in the variety *Murta* (*J. Genetics*, 37, No. 1). Very little has yet been done with the genetics of coffee, and it takes three years for the plants to mature and produce seed. The variety *Murta* has small leaves, and when selfed yields *Bourbon*, *Murta* and dwarfs in the ratio 1:2:1. *Murta* plants are therefore heterozygous for the recessive dwarf gene. *Bourbon* is somewhat taller than *Murta*, with larger leaves, and does not carry dwarfness. The gene for dwarfness is somewhat unstable, frequently mutating to tallness, and the opposite mutation, tall to dwarf, also frequently takes place.

X-Ray Mutations in Rice

A DETAILED account of X-ray mutations in rice is given by Dr. N. Parthasarathy (*J. Genetics*, 37, No. 1). The seeds of a pure line of rice were exposed to X-rays under different conditions for 1-3 hours and various types of mutations appeared. A semi-sterile mutant gave in the *F*₂ generation normal fertile plants, semi-steriles and dwarfs in the ratio 1:2:1. The semi-sterility was found to be due to the association of four chromosomes in meiosis. A chiasma was frequently present in the homologous regions proximal to the interchange in a pair of chromosomes, thus indicating crossing-over of the interchanged segments resulting in chromatid non-disjunction and abortion of 50 per cent of the pollen grains. One semi-sterile plant had two chromatin fragments, but their presence produced no visible phenotypic effect and they are rapidly eliminated in gamete formation. The dwarfs in the progeny of semi-steriles showed regular meiosis and fertile pollen with the ordinary chromosome number, but they did not set seed. Their origin is discussed and was probably due to a small deficiency or a gene mutation at or near the point of interchange. Two other mutants were trisomic. "Beaked sterile" is a primary ($2n+1$) type; while "stumpy" showed frequently a chain of five chromosomes, indicating that the extra was composed of segments derived from two non-homologous chromosomes of the haploid set.

Empirical Studies of the Seismic Phenomena of Hawaii

THIS is the title of a widely ranged study of the earthquakes of Hawaii by Austin E. Jones (*Bull. Seis. Soc. Amer.*, 28, No. 4, 513; 1938). Small earthquakes in this region are frequent and from a study of the records it appears that the greater number of *P* waves have a period of 0.3 sec. whilst there is a subsidiary maximum of 0.5 sec. The *S* waves chiefly have a period of 0.5 sec., and there exists a subsidiary maximum of waves with a 0.8-sec. period. Large periods and amplitudes appear to go together, and the upper limits of the amplitudes were found to vary with the cube of the periods, though this probably holds only for local shocks. About 60 per cent of the foci are less than 5 km. deep and 70 per cent less than 10 km. deep. Most of the deep foci are under Mauna Loa and in the Kilauea south-east rift zone. A large number of the shallow foci are in and near the Kilauea crater. The location of epicentres near and on the extension of rifts and in pronounced lines and zones suggests a larger and more numerous system of rifts than has previously been mapped. The resulting pattern of rifts about

Mauna Loa is roughly an asterisk, and the main group of epicentres is on the visible active rifts to the south-west and east-north-east of Mokuaweoweo.

Deep-Focus Earthquakes and Earth Structure near Japan

T. SHIDA discussed this subject at the opening of the Beppu Geophysical Laboratory on October 28, 1928; but it was not made generally available in Japan until 1937 (*Tikyū-Buturi (Geophys.)*, 1, 1; 1937). The author's attention was directed to the peculiarities of the earthquake of January 21, 1906, it probably having a great depth of focus; but it was not until the similar earthquake of July 27, 1926, with epicentre near the Biwa Lake, that confirmation could be obtained. The depth of focus of this latter was about 260 km., or about twice the depth of isostatic compensation as generally accepted. The preliminary tremors indicated a shock of the fracture type, and this would seem to indicate appreciable strength to a depth of, say, 300 km., where the pressure may be expected to be of the order of 100,000 atmospheres. In Japan, the origins of some deep focus earthquakes seem to lie on a line running north-west-south-east through Honshū. Shida is of the opinion that some slow process is always going on at a depth of about 300 km. in the neighbourhood of Japan, and that this is the true cause of seismic phenomena there, especially near the centre of the main island. The same author also thinks that there may be a jump in contraction of the earth's crust at a depth of about 300 km., and this may be the true cause of crustal changes and movements all over the world.

Research in Fuel Technology

AT the tenth autumn research meeting of the Institution of Gas Engineers, held in London on November 1-2, a number of papers on topical problems of the industry were received. One of them, however—the forty-third report of the Joint Research Committee of the Institution and the University of Leeds—was concerned with a possible future trend of fuel technology. This is the gasification of coal at high pressure. The report dealt with the condition under which gaseous hydrocarbons are synthesized from the elements at high pressure. It was shown that carbon, which combines only sluggishly with hydrogen at atmospheric pressure, can be caused to react freely at a red heat under pressure no higher than fifty atmospheres. Starting with coal or low-temperature coke, there is a rapid reaction with hydrogen as the temperature rises through a zone of temperature at which the structure of the coal or carbon is changing in the carbonization process. Above this temperature zone the reaction speed is greatly increased by the presence of alkali, and the results leave no doubt of the feasibility of gasifying British coal completely to yield gas of high calorific value suitable for public distribution. Moreover, the rate of gas production is much greater than currently experienced. Under some conditions, the thermal value of the gas produced per ton of coal per hour was more than fifty times greater than now obtained in gasworks practice. Naturally the supply of hydrogen is a vital factor in the economics of such a process, and this is envisaged as being obtained by the gasification of carbon with steam and oxygen under pressure. The results disclosed open the possibility of radical changes in the preparation of gaseous fuel. In such a process the gas would be generated under pressure, which would favour its wide distribution from central generating stations.

The Australian and New Zealand Association Jubilee Meeting

THE jubilee meeting of the Australian and New Zealand Association for the Advancement of Science, founded on the model of the British Association, has just ended after a most successful week of addresses and discussions at Canberra (January 11-18). It is the first time that the Association has met at the capital city of Canberra, and the meeting was probably unique by reason of the high ratio of visiting men of science to local members. Usually the meetings take place every two years at the big Australian and New Zealand cities in turn, where the visitors are lost in the large populations. Canberra is still a small garden city, and the problem of housing more than a thousand visitors was no small one.

The Australasian Association follows the British model very closely; but there are sixteen sections altogether. The president for the meeting was Prof. Ernest Scott, who delivered an address on the "History of Australian Science". The sectional presidential addresses included: Section A (Astronomy, Mathematics and Physics), "Physical Quantities", by Prof. T. Parnell; Section B (Chemistry), "The Atmosphere as a Raw Material", by W. Russell Grimwade; Section C (Geology), "Some Aspects of Glaciation in New Zealand", by Prof. R. Speight; Section D (Zoology), "The Role of Zoology in the Field of Modern Biology", by Prof. E. J. Goddard; Section E (History), "The Study of History: A Synoptic View", by Prof. R. M. Crawford; Section F (Anthropology), "Anthropology in Australia", by Prof. A. P. Elkin; Section G (Economics, Statistics and Social Science), "The Place of Expectations in Economic Theory", by L. G. Melville; Section H (Engineering and Architecture), "The Use and Convenience of Man", by Sir Henry Barraclough; Section I (Medical Science), "Physical Education in Relation to National Fitness", by Dr. E. Sydney Morris; Section J (Education, Psychology, and Philosophy), "Growing Up", by J. R. Darling; Section K (Agriculture and Forestry), "Some Aspects of Plant Pathology", by Dr. W. L. Waterhouse; Section L (Veterinary Science), "Some Modern Trends in the Study of Host-Parasite Relationships in Animal Disease", by Dr. L. B. Bull; Section M (Botany), "The Plant in Relation to Water", by Prof. J. G. Wood; Section N (Physiology), "The Protein Molecule", by Prof. W. J. Young; Section O (Pharmaceutical Science), "Some Aspects of Fifty Years Progress in Pharmaceutical Science", by Dr. E. M. Watson; Section P (Geography), "The Present Status of the Geographical Knowledge of New Guinea", by G. A. V. Stanley.

Among the more important discussions and symposia of the meeting was one on "Radio Research" (Sections A and H). A considerable liveliness in radio research is noticeable in Australia, one especially important field being the investigation of the ionosphere. Closely associated is the work of the Commonwealth Solar Observatory at Mount Stromlo, and considerable attention has been paid to the relationship between solar eruptions and radio fade-outs. Sections P and K enjoyed an excellent discussion on "Soil Erosion", a subject now of importance in Australia. This was introduced by a paper by Sir John Russell, a guest from England.

The subject was tackled from practically every point of view: pastoral, soil chemistry, and geographical and forestry aspects also came into the picture.

Another well-developed discussion in which the Botanical, Physiological and Medical and Veterinary Sections were engaged, with representatives from the Chemistry Section, covered the subject of "Virus Diseases". Needless to say, no definite conclusions were reached as to the nature of viruses (living or non-living). They were accepted as particulate, and as consisting of nucleo-proteins. One view put forward claimed them as specialized derivatives (reduction forms) of bacteria. The chemists arranged symposia on "Colloids", and on "Organic Nitrogen Compounds".

A well-attended meeting of agriculturists held a symposium on the "Pasture Problems of Australia", and the Zoology Section, for the first time in Australia, had a day devoted to "Marine Biology and Fisheries", at which several interesting original papers were read. The Zoology Section also discussed the important problem of conservation of the native fauna of Australia, and resolutions were passed which are noted below.

The geologists held five symposia: "Metasomatism of Country Rock near Ore Bodies"; "Sub-divisions of the Lower Palaeozoics in East Australia"; "The Permian Sequence in Australia"; and "Granitisation in Australia", being four of them.

It is impossible to indicate all the good work at the sections. The list of original papers shows a sustained rise in the results of research of a high standard, much of which has great economic value. Almost three hundred papers were listed for presentation at this meeting.

One of the most important meetings was a discussion covering all sections, the subject being "The Relation of Science to Society". It was opened by Sir David Rivett. This and many of the other discussions and presidential addresses were attended by the Governor-General, Lord Gowrie. The result of the discussion, at which references were made to the new activities of the British Association and of the American Association, was the formulation of several resolutions and the direction for the establishment of a committee to consider the whole subject. One recommendation was to the effect that: "In conjunction with the British and American Associations for the Advancement of Science, we wish to affirm our loyalty to the task of preserving truth, freedom of expression, and justice to the world. These are to-day subject to increasing attacks, which if successful will frustrate the future of Science and Humanity, which require that the labours of the Scientist must be utilised for the benefit and not the destruction of mankind."

Section A asked the Association to associate itself with a movement towards calendar reform.

The anthropologists asked the Association to urge the Australian Governments for funds to support the continuance of anthropological research now that the Rockefeller grants have been exhausted.

One of the most important recommendations adopted was a request from Section D, that all the Australian States should be warned of the importance

of establishing national reserves for the maintenance of the natural fauna and flora, and that these should be set up in more secluded areas and controlled and administered by experts. A request was also made for the beginning of a biological survey of Australia.

Excitement was lent to the proceedings of the Congress by two stimulating lectures given by Mr. H. G. Wells, who had been invited specially to Australia for the meeting. Mr. Wells was provocative, especially with his paper on "The Poison called History" which was delivered to the History Section; but attended by a great crowd, and much appreciated.

Other visitors specially invited from England were Sir John Flett, Sir John Russell, Prof. F. T. Brooks and Prof. N. V. Sidgwick. Prof. Brooks gave a lecture on "Epidemic Plant Diseases" and Prof. Sidgwick read a paper bearing the title "Multiple Links". Another visitor from England, Sir George Simpson, read a paper on "Electricity in Thunder Clouds" to Section A, and delivered a public lecture on "Ice Ages".

The Congress was an unqualified success, despite the terrific heat (109° in the shade one day), all records for Canberra being broken. W. J. DAKIN.

The Underground Water of London

AN excellent and serviceable memoir on "The Water Supply of the County of London from Underground Sources", prepared by Dr. Stevenson Buchan, has been issued by the Department of Scientific and Industrial Research (H.M. Stationery Office. 6s. 6d. net). It is primarily a supplementary development of the "Records of London Wells" by Messrs. Barrow and Wills, published by the Geological Survey in 1913, restricted in purview to the county boundaries and brought up to date by means of the later accumulation of information. Records of 1,080 wells are set out in detail, of which 565 make their appearance for the first time. More than one hundred of the records of strata are fully described, the remainder being in abstract form.

The memoir is commendably complete, for it gives a résumé of the history of London's water supply, with many interesting facts about the early and primitive sources from which it was drawn. So far back as 1236, water was brought to the City through conduits from wells and springs outside the populated area. Tyburn, Paddington, Hackney and Hampstead all contributed their quota during the period 1236-1549. In 1582, water was obtained from the Thames by a pump actuated by water wheels located at London Bridge. Then in 1613, the new river system was inaugurated, bringing supplies from springs in Hertfordshire, because at the beginning of the seventeenth century, the tributary streams through the town had become choked and partly buried, and few of the public wells remained. Towards the end of the eighteenth century, the first deep wells were sunk; but the movement did not make much headway for several years. Water companies were formed about the same period to draw supplies from the Thames and its tributaries, and to store it in reservoirs. These external surface sources now constitute the main feeder system.

As regards the wells, the early shallow borings were sunk to the sand and gravel terraces on the river banks. When, in course of time, these became polluted, deeper borings were made through the London Clay to the strata known as the Reading Beds and Thanet Sands, containing water either percolating from surface outcrops outside London or derived from the underlying chalk, which, acting as an enormous reservoir, to-day is the most important water-bearing bed under London. The water-level, however, is falling both in the sands (some supplies are actually exhausted in the northern area) and in

the chalk, whence water is being extracted more rapidly than the rate of replenishment by the extremely slow flow which is alone possible under existing subterranean conditions.

As examples, the memoir mentions the wells close to the National Gallery, which, at one time, supplied the fountains in Trafalgar Square, many of the public buildings in Whitehall, the old Millbank Prison and the Houses of Parliament. Between 1844 and 1911, the water-level had fallen 127 ft., and the wells were shortly afterwards abandoned. Another well, which used to feed the Serpentine and its fountains, the Palace Lake and the lake in St. James's Park, had its water-level lowered by 96 ft. in the space of forty-eight years and was also abandoned.

With the increase in pumping and the growing competition for supplies, the lowering of the water-level is becoming more and more pronounced. New wells in the district of chalk outcrop are tapping quantities of water which might otherwise travel towards the centre of London. Moreover, land drainage over the surface of the outcrop is now more efficient and the quantity of rainfall available for absorption correspondingly diminished, both from this cause and also from the increase in impermeable surface due to building and road making. Finally, the prolonged periods of drought in recent years have exercised their adverse influence in preventing the recovery of lost levels. With the depression in level, there has been manifested an increase in salt water pollution of many wells down river from Bermondsey.

Wells have been sunk below the chalk to the Old Red Sandstone, the deepest of which is a well at Stonebridge Park, with a depth of 2,225 ft. Unfortunately, after encountering traces of oil and gas from levels below 1,600 ft., the final yield was small and distinctly saline.

The following conclusions are drawn as to the future of supplies from the chalk-sand reservoir under the County of London. The fall in water-level is likely to continue and the annual rate of depression to increase. If a uniform, or slightly increased rate of fall be assumed, the water will reach the base of the Upper Chalk in many parts of London during the present generation, and, at this level, it is probable that a negligible amount of water will be obtainable from the wells. There is, moreover, little likelihood of a supplementary supply from the beds below the Chalk under London.

BRYSSON CUNNINGHAM.

Academy of Sciences of the U.S.S.R.

THE election of members and member-correspondents of the Academy of Sciences of the U.S.S.R. took place in Moscow on January 28-29 at a general session of the Academy. Altogether fifty-six new academicians and a hundred and two member-correspondents were elected, the following being a list of those of scientific interest.

DEPARTMENT OF TECHNICAL SCIENCES

Mechanics: Dr. N. I. Muskhelishvili, president of the Georgian Branch of the Academy of Sciences of the U.S.S.R., founder of a Soviet school in the theory of elasticity; Prof. N. E. Kochin (University of Moscow), a well-known authority on hydrodynamics; Prof. E. A. Chudakov (Bauman Mechanico-Machine Building Institute, Moscow), author of numerous works on automobile engineering.

Mining: Prof. L. D. Sheviakov; Prof. A. P. German, an expert on mining mechanics.

Technical Physics: Dr. N. D. Papalexi, an authority on theoretical and experimental radio-engineering; Dr. M. V. Shuleikin, an authority on radio-communications; Dr. V. P. Linnik, noted for his research in technical optics.

Energetics: Prof. M. V. Kirpichev (Molotov Institute of Energetics in Moscow), an authority on heat engineering; V. P. Nikitin, director of the Bauman Mechanico-Machine Building Institute of Moscow, an authority on electrical welding; Prof. V. S. Kulebakin (Zhukovsky Military Aviation Academy), known for his work on electro-technics.

Metallurgy: Dr. N. P. Chishevsky, noted for his researches in the technology of metallurgical fuel; Prof. N. T. Gudtsov (Leningrad Industrial Institute), noted for his work on special steels.

Transport (hitherto not represented in the Department): Dr. V. N. Obrastsov, an authority on the planning of railway stations and junctions; Dr. V. L. Poedunin, known for his work on theoretical and practical questions relating to shipbuilding.

The following member-correspondents were also elected: G. V. Akimov, P. F. Antipin, I. I. Artobolevsky, I. M. Bakhurin, N. M. Beliayev, A. A. Bochvar, I. S. Bruk, N. G. Bruyevich, A. B. Chernyshev, D. M. Chikhikov, S. A. Christianovich, Z. F. Chukhanov, N. M. Gerasimov, A. V. Gorinov, A. S. Ilyichev, M. A. Kapeliushnikov, M. M. Karnaukhov, V. I. Kovalenko, M. P. Kostenko, A. B. Lebedev, G. P. Peredery, A. S. Predvoditelev, L. N. Sretenaky, S. S. Steinberg, M. A. Velikanov, V. P. Vologdin, I. N. Voronovskiy, B. M. Vul and V. V. Zvonkov.

DEPARTMENT OF MATHEMATICAL AND NATURAL SCIENCES

Physico-Mathematical Sciences: Dr. S. L. Sobolev; Dr. A. N. Kolmogorov; Prof. V. A. Fok (University of Leningrad); Dr. P. L. Kapitza, director of the Institute of Physical Problems of the Academy of Sciences; G. A. Shain, astronomer at the Simeiz Observatory.

Chemistry: Prof. S. S. Nametkin (University of Moscow), author of a number of works on oils and synthetic aromatic substances; Dr. A. P. Orekhov, noted for his research in alkaloids; Prof. P. P. Shorin (Stalin Industrial Academy), noted for his work on the creation of artificial fibres; Dr. V. G. Khlopin,

director of the Radium Institute of the Academy of Sciences; Dr. A. N. Terenin, noted for his research in the complex processes of photographic chemistry.

Geology and Geography: Dr. M. A. Uslov, authority on the mineralogy of Western Siberia; Dr. P. I. Stepanov, authority on coal deposits of the U.S.S.R., particularly of the deposits in the Donets Basin; Dr. A. N. Zavaritsky, noted for his work on the ore deposits of the Urals; Dr. P. P. Shirshov, who took part in the North Polar Expedition on the drifting ice-floe of 1937-38; Dr. A. A. Grigorev, known for his work in physical geography.

Biology: Dr. T. D. Lyssenko, noted for his work on vernalization; Dr. N. V. Taitain, known for his work in obtaining a hardy perennial wheat by crossing winter wheat with couch grass; Dr. L. S. Stern (the only woman academician elected), and Dr. I. S. Beritashvili, both noted for their original work in physiology; Dr. E. N. Pavlovsky, director of the Tajikistan base of the Academy of Sciences, noted for his research in applied zoology; Dr. K. I. Skriabin, an outstanding authority on veterinary science.

Medicine (this is the first time that representatives of medicine have been elected to the Academy): Drs. N. N. Burdenko, A. I. Abrikosov, M. I. Auerbach, N. N. Anichkov and A. D. Speransky.

Dr. Y. M. Shokalaky, known for his work in geography, was elected an honorary member of the Academy.

The following member-correspondents were also elected:

Physico-Mathematical Sciences: A. I. Alikhanov, V. A. Ambartsumian, S. I. Beliaevsky, A. O. Gelfond, A. Y. Khinchin, A. A. Lebedev, M. A. Leontovich, L. S. Pontriagin, I. I. Privalov, D. V. Skobelstin.

Chemical Sciences: P. P. Budnikov, N. A. Izgarishv, A. F. Kapustinsky, I. A. Kazarnovsky, A. N. Nesmeyanov; N. I. Nikitin, V. M. Rodionov, S. Z. Roginsky, G. G. Urazov, S. I. Volkovich.

Geology-Geographical Sciences: N. N. Baransky, E. K. Fedorov, S. F. Fedorov, I. F. Grigoriev, F. N. Krasovskiy, P. I. Lebedev, F. P. Savarensky, S. S. Smirnov, A. N. Tikhonov, A. G. Vologdin.

Biology: E. A. Asratian, V. P. Bushinsky, V. A. Dogel, A. A. Grossheim, K. S. Koshtoyants, A. I. Oparin.

Medicine: N. F. Garmaleya, N. I. Grahenkov, P. A. Herzen, M. B. Krol, B. I. Lavrentiev, V. P. Osipov, N. N. Petrov, O. N. Podvysotskaya.

Early in February, reorganization of the Academy of Sciences was discussed in connexion with the election of the large number of new academicians and member-correspondents enumerated above, as well as the substantial changes that have taken place in the structure of the Academy itself. As against the previous three departments—Department of Technical Sciences, Department of Mathematical and Natural Sciences, Department of Social Sciences—eight departments are being formed, namely: Department of Physico-Mathematical Sciences, Department of Chemistry, Department of Geology and Geography, Department of Biology, Department of Technical Sciences, Department of History and Philosophy, Department of Economics and Law, Department of Languages and Literature.

Paris Academy of Sciences

Annual Prize Awards

AT the annual public meeting of the Paris Academy of Sciences held on December 19, M. Aimé Cotton, president, announced the following prize awards:

Mathematics. Poncelet Prize to Prof. S. Mandelbrojt, for the whole of his work on analytical functions. Francœur Prize to Prof. J. Dieudonné, for his work on the theory of functions.

Mechanics. Montyon Prize to Prof. L. Couffignal, for his work on mechanisms. Fourneyron Prize to V. Hégly, for researches in hydraulics. Henri de Parville Prize to Mme. M.-L. Dubreil-Jacotin, for her work on periodic waves. Henry Basin Foundation (5,000 francs) to M. Mennesson, for his work on the utilization of pneumatic currents for the measurement of lengths and thicknesses.

Astronomy. Lalande Prize to A. Lallemand, for his work on physical astronomy. Damoiseau Prize to H. Fabre, for his work on recurrent movements in celestial mechanics. Benjamin Valz Prize to P. Lacroute, for his work on physical astronomy. Janssen Medal to B. Lindblad, of Stockholm, for his work in theoretical and physical astronomy. La Caille Prize to P. Baize, for his work on visual double stars. Antoinette Janssen Foundation (5,000 francs annually for 1938-42) to V. Kourganoff, for his work on theoretical astronomy.

Geography. Delalande-Guerineau Prize to J. Soubrier, for the whole of his travels in the Sahara, French West Africa and Liberia, northern Albania, Kurdistan and Iraq. Gay Prize to A. Romer, for the organization and starting of the Geophysical Observatory of Martinique and for his observations on Mont Pelée. Tshihatchef Foundation to P. Carton, for his work on the meteorology of Indo-China. Binoux Prize to Capt. A. Nandillon, for the whole of his work on applications of acoustics to navigation.

Navigation. Plumey Prize to M. Serruys, for his work on internal combustion motors.

Physics. L. La Caze Prize to Prof. H. Ollivier, for his work on the relations of magnetism and magnetic rotatory polarization. François Hébert Prize to M. Halesinsky, for his work on atomicity and chemistry. Hughes Prize to P. Girard, for his work on the measurement of dielectric constants. Danton Foundation to P. Lambert, for his researches on radiation. Clément-Félix Foundation to R. Freymann, for his work on infra-red radiation. Général Ferrié Foundation to F. Bedeau, for his work on high-frequency waves.

Chemistry. Montyon Prize (Unhealthy Trades), a prize (2,500 francs) to the late R. Schmutz, for his work on hygiene and passive defence, in particular that which concerns the detection of gases; an honourable mention (1,500 francs) to G. Courtois, who has taken an active part in perfecting apparatus for protection against noxious gases. Jecker Prize to Prof. A. Wahl, for his work on colouring matters and, in particular, on the indigoids. L. La Caze Prize to Prof. P. Jolibois, for inorganic chemistry. Cahours Foundation to R. Guillemet, for his work on [biological] chemical analysis. Housseau Prize to M. Badoche, for his work on bodies of the rubrene family and for his measurements of heats of combustion of numerous nitrated derivatives. Oh. Adam

Girard Foundation to Prof. R. Quelet, for his work in organic chemistry.

Mineralogy and Geology. Fontannes Prize to L. and J. Morellet, for their paleontological studies of the tertiary areas of the Paris region. André-O. Bonnet Prize (paleontology) to J. Piveteau, for the whole of his paleontological work and notably for his memoir "Paléontologie de Madagascar, XXII. Un Amphibien du Trias inférieur. Essai sur l'origine et l'évolution des Amphibiens Anoures". James Hall Prize to J. Goguel, for a thesis entitled "Description tectonique de la bordure des Alpes, de la Bléone au Var".

Geophysics. Victor Raulin Prize to G. Grenet and J. Coulomb, for their work on electrically registering seismographs.

Botany. Desmazières Prize to J. Feldmann, for his researches in algology. Montagne Prize to R. Heim, for his researches on the Agaricimae. De Coincy Prize to Mlle. M.-T. Gertrude, for her work on the morphogenesis of *Veronica Anagallis*.

Rural Economy. Paul Marguerite de la Charlonie Prize to Prof. V. Ducomet and E. Foëx, for their researches on plant pathology and genetics during the past twenty years on the potato.

Anatomy and Zoology. Cuvier Prize to G. Seurat, for the whole of his zoological work. Savigny Foundation to C. Crossland, director of the Zoological Station of the Egyptian University at Ghardaqa, for his researches on the fauna of the Red Sea. Jean Thore Prize to T. Monod, for his work on Crustacea.

Anthropology. André-O. Bonnet Prize to Prof. E. Dubois (Amsterdam), for his discovery of *Pithecanthropus* in Java and his researches on the phylogenetic development of the brain.

Medicine and Surgery. Montyon Prizes (2,500 francs) to Prof. L. Binet and G. Weller, for their book "Le Glutathion"; Prof. A. Pettit, for his book "Sérothérapie antipoliomyélitique d'origine animale"; F. Trens, for the whole of his work on paludal serology. Honourable Mentions (1,500 francs) to Prof. M. Barthélemy, for his book "Les diagnostics chirurgicaux au lit du malade"; A. Bensaude, for his book "L'évolution cancéreuse des tumeurs bénignes du rectum. Son importance pour la prophylaxie du cancer du rectum"; Mlle. M. Ladet, for her book "Le syndrome malin au cours des toxi-infections". Barbier Prize to Prof. L. Courty and M. Ansel, for their work "Le traitement chirurgical du goitre exophtalmique et des goitres avec hyperthyroïdisme". Bréant Prize to P. Remlinger and J.-E. Bailly, for their work "Contribution à l'étude du virus de la maladie d'Anjesky". Godard Prize, no award. Mège Prize (1,000 francs) to A. Donatien and F. Lestoquard, for their work concerning animal rickets. Bellion Prize to Prof. P. Coulouma, for his work "La terminaison des nerfs pneumogastriques et ses variations. Étude d'anatomie descriptive comparée chez l'homme et dans la série des Vertébrés", and the whole of his anatomical work. Baron Larrey Prize to Colonel M. Liégeois, for his memoir relating to the general etiology of scarlatina, its modes of propagation, its prophylaxy and its therapy. Jean Dagnan-Bouveret Prize (5,000 francs) to Mme. A. Randoin (née L. Fandard), for the whole of her researches on the physiology of nutrition.

5,000 francs to X. Henry, for his method of diagnosing paludism called melano-flocculation; 4,000 francs to L. Delhoume, for his work "L'École de Dupuytren: Jean Cruveilhier et Claude Bernard: pensées".

Cancer and Tuberculosis. Roy-Vaucouloux Prize to V. Vilter, for his researches on the physiological mechanism of the variations of colour of amphibians and fish. Louise Darraq Prize, awarded for work in the fight against cancer, to A. Peyron and his co-laborators of the Institut Pasteur, for the whole of their work. Eugène et Amélie Dupuis Prize, not awarded.

Physiology. Montyon Prize to M. Fontaine, for the whole of his work. L. La Caze Prize to Prof. A. Mayer, for the whole of his work. Pourat Prize to M. Florkin, for his work "Physiologie comparée du milieu intérieur dans la série animale". Martin-Damourette Prize to R. Duffau, for his work "Avitamines et Métabolisme glucidique musculaire".

Statistics. Montyon Prize (1,000 francs) to H. Bunle, for the whole of his statistical work; and 1,000 francs to Prof. G. Ichok, for his work "La mortalité à Paris et dans le département de la Seine".

History and Philosophy of the Sciences. Binoux Prize: 2,000 francs to Prof. A. Seamat, for his works "Le système absolu classique et les mouvements réels" and "Les systèmes privilégiés de la physique relativiste"; 1,500 francs to J. Torlais, for his work "Réamur".

Works of Science. Henri de Parville Prize: 2,500 francs to A. Danjon and A. Couder, for their work "Lunettes et télescopes. Théorie. Conditions d'emploi. Description. Réglage"; 2,000 francs to M. Duportet, towards his work on the topobibliography of France, of which three volumes have appeared.

Medals. Berthelot Medals to the late R. Schmutz, M. Badoche, and R. Quelet.

General Prizes. State Prize (Grand Prize of the Mathematical Sciences) to Prof. J. Favard, for his work in algebra and geometry. Bordin Prize to H. Scholler, for his geological work in the Alps and his hydrogeological researches in Tunisia. Lallemand Prize to A. Fessard, for his researches on the rhythmic functions of the nerves. Serres Prize to Prof. R. Courrier, for his work on the genital function in mammals. Vaillant Prize to Prof. L. Bounoure, for his researches on the embryogeny of amphibians. Estrade-Deloros Prize to Prof. J. Jolly, for the whole of his histophysiological work. Houlléviague Prize to B. Lyot, for his work on the solar corona. Saintour Prize to A. de Cugnae, for his work on the Gramineae. Jules Mahyer Prize to R. Echevin, for his work on plant physiology. Lonchampt Prize to J. Levollay, for his work on the biochemistry of magnesium. Henry Wilde Prize to H. Huhubei, for his discovery of element 87, belonging to the series of alkali metals. Caméré Prize to Prof. L. Grelot, for his contribution to the progress attained in the construction of metal and reinforced concrete bridges. Gustave Roux Prize to Prof. H. Vigreux, for his work "Le soufflage du verre dans les laboratoires scientifiques et industriels". Thorlet Prize, not awarded. Albert I^{er} le Monaco Prize to Prof. A. Denjoy, for the whole of his mathematical work. Marquet Prize to Prof. R. Bricard, for his work in geometry. Général Muteau Prize to Prof. H. Abraham, for his work in electricity, principally for apparatus he has devised, some of which has been used in national defence, and for progress made in high precision measurements.

Priz des Grandes Ecoles. Laplace Prize to R. Joison. L.-E. Rivot Prize between R. Loison (750 francs), L. Boucheny (500 francs), A. Pages (750 francs) and P. Olos (500 francs).

GENERAL FUNDS FOR SCIENTIFIC RESEARCHES

Trémont Foundation to Mme. L. Nouvel, for her work "Contribution à l'étude de la mue, de la croissance et de la régénération chez les Crustacés Natantia".

Gegner Foundation to M. Aubert, for his researches on internal combustion motors.

Jérôme Ponti Foundation to Prof. J. Pères, for his work on the mechanics of fluids.

Hirn Foundation to Prof. H. Chrétien, for his researches on optical instruments.

Henri Becquerel Foundation to Prof. P. Delens, for his work on analysis and geometry.

Loutrouil Foundation (total grants, 117,500 francs).

Researches on set problems. 3,000 francs to Mlle. F. Bloch, for work on cutaneous tuberculosis; 2,000 francs to A. Brizard and R. Florio, for researches on dermatoses of the horse and of the dog; 7,500 francs to D. Chalonge, D. Barbier and A. Arnulf, for work at the international scientific station at the Jungfrauoch; 6,000 francs to Prof. L. Daniel, for work on the pedigree culture of the Jerusalem artichoke; 3,000 francs to Prof. R. Dubrissay, for studies of the action of sulphur on different metals, and notably silver; 5,000 francs to A. F. de Lapparent, for work on the Dinosaurs of the south of France; 2,000 francs to Prof. A. Métrol, for work on the improvement of output of heat engines by the transformation into reactive energy of the potential and kinetic energy of the exhaust gases; 5,000 francs to Prof. M. Pierre, for researches on the regulatory mechanism of calcæmia and of phosphatæmia in the domestic animals.

Researches to be carried out in France Overseas. 8,000 francs to A. Lasserre, for work on terrestrial magnetism in Algeria and the Algerian Far South.

Purchase of laboratory material. 4,000 francs to Prof. F. Diéart, for apparatus for utilising geophysical methods for the study of subterranean currents; 5,000 francs to Prof. P. Fleury, for a Moll double thermo-converter, for the study of the photometry of incandescent lamps fed with alternating current; 3,000 francs to Prof. P. Frémy, for a photomicrographic apparatus; 3,000 francs to Prof. P. Lamare, for a precision balance; 2,000 francs to Prof. J. Lefèvre, for microphotography material; 10,000 francs to Prof. E. Marchoux, as a contribution towards a Feussner spectrograph installed at the Pasteur Institute; 9,000 francs to P. Teilhard de Chardin, as a contribution towards the equipment of his laboratory for advanced studies in human paleontology.

Libraries. 7,000 francs to the National Veterinary School of Alfort, for the purchase of periodicals; 7,000 francs to the National Veterinary School of Lyons, for the purchase of books and foreign periodicals; 2,000 francs to the National Veterinary School of Toulouse, for the purchase of books and scientific publications; 2,000 francs to the National Agronomic Institute, for the acquisition of foreign periodicals.

Publications. 8,000 francs to the Comité de physique du globe des colonies, as a contribution to the publication of the *Annales de physique du Globe de la France d'Outre-Mer*; 3,000 francs to P. Chabanaud, for the publication and illustration of works on the morphology of non-symmetric teleosts; 3,000 francs to G. Guilbert, for printing a work entitled "L'Orage, sa genèse, ses mystères, sa prévision"; 8,000 francs to Prof. P. Lemoine, to assist in the publication of a geological study of Mauritius.

Mme. Victor Noury Foundation (four prizes of 2,500 francs each): A. Lenoble, for his researches on

the chronological succession of the volcanic eruptions of central Madagascar, the age of the *coulées* of the east side and his discovery of organic remains in the Cristallophyllian of the island; Prof. A. Luquet, for his biogeographical work and particularly for that concerning the Central Massif; E. Thallier, for his work on the magnetisation of clays and of burnt earthenware, with application to the study of the evolution of the terrestrial magnetic field; P. Vintemberger, for his researches in experimental embryology.

Millet-Ronssein Foundation: 4,000 francs to A. Balachowsky, for his work on agricultural entomology, and in particular for his book "*Les Insectes nuisibles aux Plantes cultivées*", published in collaboration with L. Mesnil; 3,000 francs to Prof. A. Carpentier, for his paleobotanical work, and particularly for that concerning the oil earthenware of the north of France and of the Central Massif, the Permian, the Jurassic and the Cretaceous of France, Morocco and Madagascar; 3,000 francs to Prof. H. Chermeson, for his work on the Cyperaceae and the flora of Madagascar.

Villemot Foundation: 12,000 francs to L. Blaringhem, for the installation at the Gaston Allard Arboretum, at Angers, of an exact electrically heated bed; 14,000 francs to Mlle. G. Cousin, for the purchases of stoves; 10,000 francs to G. Deflandre, for the purchase of microscope objectives; 12,500 francs to Prof. L. Dumoyer, for the purchase of a Ribaud optical micropycrometer; 5,500 francs to E. Esclançon, for the construction of a double clock with two dials, indicating simultaneously, with very high precision, mean solar time and mean sidereal time; 15,000 francs to Prof. H. Guillon, for perfecting an apparatus for the measurement of high temperatures of gases by the method of aspiration pyrometry; 10,000 francs to C. Harnist, for his projected researches on the manufacture of sulphuric acid from gypsum; 10,000 francs to the Institut Marey, for researches on the ultra-rapid cinematography and ocellographic recording of the nerve influx; 25,000 francs to P. Lejay, director of the Observatory of Zi-Ka-Wei, for his researches on the application of the inverted electrical pendulum to the precise determination of the inclination of the axes of astronomical instruments; 10,000 francs to Prof. M. Machébeuf, for his researches on the chemical phenomena of immunity; 15,000 francs to R. Martin, for perfecting thermochemical material intended for the determination of the quantity of energy resulting from the chief combustions and reactions utilized in industry; 8,000 francs to A. Peyron, for his experimental and comparative studies of the pathology of tumours; 20,000 francs to A. Savornin, for the purchase of an inclination needle for absolute magnetic measurements; 12,000 francs to H. Vincent, for the purchase of reactive experimental animals for his researches on the pathogeny of certain infectious maladies and the conditions of immunity; 10,000 francs to R. Wurmsier, for the purchase of experimental animals.

Charles Frémont Foundation to C. Berthelot, for his works "*Technique et Économie nouvelles des carburants de synthèse*" and "*Épuration, séchage, agglomération et broyage du charbon*".

SPECIAL FOUNDATIONS

Lannelongue Foundation to Mme. G. Cusco; Girbal-Baral Foundation (10,000 francs each) to F. Marty and F. Roger; D'Aumale Prizes (5,000 francs each) to the widow of C. Gravier and the daughter of the late C. Flahault.

Science News a Century Ago

Samuel Cunard and Robert Napier

THE long connexion of Robert Napier with the Cunard Steamship Company, for which he built eighteen trans-Atlantic steamships, began with two letters, one written by Samuel Cunard on February 25, 1839, and the other, Napier's reply written three days later. Writing from Piccadilly to his Glasgow agents Cunard said, "I shall require one or two steamboats of 300 horse power and about 800 tons. I am told that Messrs. Wood and Napier are highly respectable builders and likely to be enabled to fulfil any engagement that may enter into." In his reply to Cunard's agents, Napier said, referring to the price, "I have done them as low as £35 per ton of total measurement of the vessel, and I have got above £50 per ton for some others. I may, however, state that good vessels, warranted to stand any inspection and give entire satisfaction both as to the vessel and machinery, cannot be done for less than from £40 to £42 per ton—this for the vessel ready for sea, with cabins, sails, rigging, anchors, cables, etc. . . ."

After further negotiations a contract was arranged for the construction of the four vessels, *Acadia*, *Britannia*, *Caledonia* and *Columbia*. The *Britannia*, 1,150 tons, 420 horse-power, was the first finished, and she sailed on her maiden voyage from Liverpool to Boston, July 4, 1840.

University College, London

THE annual meeting of the proprietors of University College was held on February 27, 1839. The chief topic handled in the report of the Council, said the *Athenaeum* of March 2, was the regulations of the University dealing with the degree in arts. From the report it added, "we learn that the Exhibitions offered by the Government as a reward for proficiency in passing the matriculation examination have been divided between students of University College and King's College." Among the novelties announced were the class for schoolmasters, the class for civil engineers and the school for practical chemistry; the erection of a spacious building for the practice of anatomy, and the fitting up of a large room as a library for medical students. In 1837-38 there were 497 students in medicine, 142 in arts and 387 boys in the Junior School.

Prof. W. T. Brande as a Lecturer

ON March 1, 1839, Faraday's colleague at the Royal Institution, Prof. William Thomas Brande (1788-1866), gave a lecture on steel, a report of which appeared in the *Mechanics' Magazine* of March 16, 1839. The report concluded with saying, "No one will question the great ability of Mr. Brande as a lecturer, but we could almost indulge the wicked wish of being able to tamper with, and manœuvre a little, the progress of the clock in order to see the good effect for once of surprising him out of the extreme deliberateness of his delivery. . . . Unfortunately, also he does not think it necessary to raise his voice higher than in common conversation, but though his enunciation is so beautifully distinct, that with listening attention, he may be heard in most parts of the theatre, yet the continued effect to give such attention, especially at this time of the year, when everybody thinks it his duty to cough, soon becomes very fatiguing, and at last so painful as quite to mar the pleasure of hearing him lecture."

Societies and Academies

Edinburgh

Royal Society of Edinburgh, February 6.

P. A. M. DIRAC: The relation between mathematics and physics (Address). In setting up a theory of natural phenomena, one strives in the first place for simplicity; but it seems that mathematical beauty is really a more important quality than simplicity. It is difficult to put any limitation on the extent to which mathematics applies to the description of the universe, and one is led to think that it must apply to everything. In such a complete scheme one could scarcely expect simplicity, but one may well have beauty. The discussion of these questions is much influenced by modern advances in quantum mechanics and in cosmological theory.

R. A. ROBB and T. R. TANNAHILL: Lunar atmospheric pressure variations at Glasgow. The Glasgow barograph records of 1868-1912 have been examined for the determination of the lunar atmospheric tide at Glasgow. It is found that on barometrically quiet days there exists a local lunar variation, mainly diurnal in character, not predicted by theory. The diurnal component appears to increase progressively with quietness of day. Removal of this variation results in a probable value of the normal lunar tide of:

$$0.0110 \sin (2\theta + 60^\circ) \text{ millibar,}$$

θ being reckoned from upper lunar transit.

Paris

Academy of Sciences (C.R., 208, 237-312, Jan. 23, 1939).*

L. DOMANGE: Stability of manganic sulphate in aqueous solutions of sulphuric acid.

MILLES, M. MONTAGNE and Y. ISAMBERT: Action of ethylmagnesium bromide on butyric ethylanilide.

P. GRAMMATICAKIS: Secondary reactions observed in the course of the condensation of organo-magnesium compounds with phenylhydrazones.

L. PALFRAY, S. SABETAY and A. HALASE: Preparation of some alkoxy- and arylalkoxyethanols and higher homologues.

E. A. DE LA RÛN: Contribution to the mineralogical study of the coast of French Somaliland.

A. MICHEL-LÉVY and J. WYART: Synthesis of ortho- and of albite by pneumatolysis with the aid of explosives.

E. DESGUIN and A. DAUVILLIER: Origin of life.

P. DANGHARD: The alga *Vaucheria* observed in the region of the south-west [of France], and a new species of this genus.

G. LAISNÉ: Variations of the osmotic pressure of tissue sugar of *Fraxinus excelsior* L. and of some other plants in the course of artificial haymaking.

J. LÉVYRE: Similarity of the cytological effects exerted by phenylurethane and colchicine on plants.

J. COMANDON and P. DE FONBRUNE: Preparation and mode of action of traps of predatory fungi for nematodes; investigations by the aid of micro-manipulation and cinematography.

R. GIRARD: A case of evolution of *Hypoderma botis* De Geer on the horse.

M. PIETTRE: Conditions of preparation, at low temperatures, of crystalline oxyhaemoglobin.

G. MOURIQUAND: Resistance to avitaminosis.

(*Continued from p. 307)

Cracow

Polish Academy of Sciences and Letters (C.R., *Classica Sci. Math. et Nat.*, Jan. 9, 1938).

W. FRIEDBERG: Attempt at a stratigraphy of the Miocene of Poland, based on the molluscan fauna (2).

F. ROGOWSKI: (1) Chlorophyll and the carotinoids of some marine algae (from the Gulf of Naples). Carotinoids are present in relatively large quantities in brown and green algae, but in small quantities in red algae. Chlorophyll is low in brown and red algae, while in certain green algae the quantity is greater than in many land plants. (2) Chlorophyll in the digestion of larvae of certain Lepidoptera. Gravimetric estimation of the chlorophyll in the excrement of certain Lepidoptera shows that it is present in considerable quantity and unaltered in form.

W. SWIENTY: Blood vessels in the ventral fins of certain teleosts.

A. KOZŁOWSKI: Researches on the summer eggs of aphids. Synchronous and heterochronous segmentation are found in these parthenogenetic eggs up to the sixth division. During the seventh division and later, synchronous division of all the cells was never observed.

Dublin

Royal Irish Academy

R. LLOYD PRAeger: A further contribution to the flora of Ireland. This is an epitome of recent advances in our knowledge of the flora of Ireland, so far as the higher plants are concerned, and forms a supplement to the census of the Irish flora which was given in "The Botanist in Ireland" published in 1934.

Tokyo

Imperial Academy (Proc., 14, No. 10, 359-397; 1938).

KOSAKU YOSIDA, YUKIO MIMURA and SHIZUO KAKUTANI: Integral operator with bounded kernel.

KOSAKU YOSIDA: Operator-theoretical treatment of Markoff's process.

MASAO INOUE: Process of constructing the solution to Dirichlet's problem.

KIISIN SUEUKI, MASAAKI HIRUHATA and GORÔ KUBOIIWA: Photographic observations of new variables and some known variables in Cygni. With the 10-cm. triplet camera attached to the 20-cm. refractor at the Tokyo Science Museum, 125 photographs were taken around α and η Cygni.

KOJI HIDAKA: (1) Horizontal oscillations of bay water induced by tidal currents. (2) Free oscillation of water in an oval basin.

SHÔSHIRÔ HANEKAWA: Studies on the foraminiferal fauna found in the bore cores from the deep well in Kita-Daitô-Zima (North Borodino Island). The following characteristics were examined: (a) lithological character of the bore cores; (b) organic contents and the state of preservation of fossils; (c) distribution of the foraminiferal fauna in the bore core and their stratigraphical ranges; geological ages of the bore cores.

TORANOSUKE SUGIURA: A list of chromosome numbers in angiospermous plants. (5). Species from eighteen families are given.

TOKI-O YAMAMOTO: Distribution of temperature constants in *Oryzias latipes*.

SEIGO FUNAKO and NORITOKI SAITO: Study of lymph.

Forthcoming Events

[Meetings marked with an asterisk are open to the public.]

Monday, February 27

UNIVERSITY COLLEGE, LONDON, at 5.—Dr. L. Young: "Animal Detoxication Mechanism" (succeeding lectures on March 6 and 13).*

Tuesday, February 28

UNIVERSITY COLLEGE, LONDON, at 5.15.—Dr. W. E. Swinton: "The Use of Museums. (4) Natural History in Museums".*

CHADWICK PUBLIC LECTURE (at the Royal Society of Tropical Medicine and Hygiene), at 5.30.—Prof. Major Greenwood, F.R.S.: "Occupational and Economic Factors of Mortality".*

GRISHAM COLLEGE, at 6.—A. R. Hinks, F.R.S.: "Different Kinds of Nebulae" (Gresham Lectures on Astronomy. Succeeding lectures on March 1, 2 and 3).*

ROYAL PHOTOGRAPHIC SOCIETY (SCIENTIFIC AND TECHNICAL GROUP), at 7.—Annual General Meeting.

Wednesday, March 1

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section). Symposium of papers on "Direction Finders" presented by Dr. R. L. Smith-Rose.

Thursday, March 2

CHEMICAL SOCIETY (at the Imperial College of Science and Technology), at 5.30.—Symposium on "Micro-technique in Organic Chemistry" to be opened by Prof. I. M. Heilbron, F.R.S.

Friday, March 3

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at the Institute of Chemistry, 30 Russell Square, W.C.1), at 5.—Annual General Meeting.

Sir Henry Dale, F.R.S.: "Biological Standardization".

UNIVERSITY COLLEGE, LONDON, at 5.15.—K. de B. Codrington: "The Use of Museums. (5) Museums, Past and Future".*

GEOLOGISTS' ASSOCIATION (at University College, London), at 7.30.—Annual General Meeting.

Prof. H. L. Hawkins, F.R.S.: "A Short History of Sea-Urchins".

ROYAL INSTITUTION, at 9.—Sir William Bragg, O.M., F.R.S.: "Liquid Films".

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

CHEMIST at the Royal Gunpowder Factory, Waltham Abbey—The Principal Clerk, Royal Gunpowder and Small Arms Factories, Hatfield Lock, Middlesex (March 3).

TEACHER OF TELECOMMUNICATIONS AND PHYSICS in Woolwich Polytechnic, London, S.E.18—The Secretary (March 3).

HEAD OF THE DEPARTMENT OF CHEMISTRY in Bradford Technical College—The Director of Education, Town Hall, Bradford (March 4).

ASSISTANT NATURALIST in the Millport Marine Laboratory—The Secretary, Scottish Marine Biological Association, 185 St. Vincent Street, Glasgow, G.2 (March 6).

JUNIOR SCIENTIFIC OFFICER in the External Ballistics Department of the Ordnance Board, Royal Arsenal, Woolwich, London, S.E.18—The Secretary (March 8).

SCIENTIFIC OFFICER (physics or engineering) in the Air Ministry Scientific Research Pool—The Under-Secretary of State, Air Ministry (S.E.D.), Berkeley Square House, London, W.1 (March 11).

PROFESSOR OF MATHEMATICS in the University of Durham (Durham Division)—The Registrar (March 16).

EXAMINERS in various science subjects for the Matriculation and General School Examination of the University of London—The Secretary to the Matriculation and School Examinations Council, University of London, W.C.1 (March 17).

ASSISTANT CIVIL ENGINEER in the Civil Engineer-in-Chief's Department of the Admiralty—The Civil Engineer-in-Chief, Admiralty, S.W.1.

ASSISTANT INSTRUCTOR in ENGINEERING in a new trade school in Hong Kong—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 (2/78306).

RESEARCH OFFICER to the Tyneside Council of Social Service—The Director, 17 Ellison Place, Newcastle-upon-Tyne.

No. 3618

The Spens Report and Technical Education

WHEN the report of the Board of Education's Consultative Committee on the Education of the Adolescent (afterwards known as the Hadow Report) was noticed in these columns (NATURE, Feb. 5, 1927), we recorded our regret that the position and importance of the junior technical school had not received adequate treatment. No such charge can be made against the Committee's recent report, now already widely known as the Spens report (see also NATURE of January 21, p. 103, and February 18, p. 259, and p. 363 of this issue).

An outstanding recommendation is that there be established a new type of higher school of technical character quite distinct from the traditional academic grammar school, and as a first step towards that end "a number of existing junior technical schools oriented towards the engineering and building industries and any other technical schools which may develop training of such a character as (a) to provide a good intellectual discipline altogether apart from its technical value, and (b) to have a technical value in relation not to one particular occupation but to a group of occupations should be converted into technical high schools".

It is the intention of the Committee that these schools shall be accorded, in every respect, equality of status with schools of the grammar school type. Clearly, if that intention is to be carried out, there must be equality in respect of the age of entry. Hitherto the age of entry into the junior technical school has been thirteen plus. That has meant that, since the secondary (grammar) schools recruited at the age of eleven, they have had the opportunity of taking the cream of the pupils before the junior technical school could have its chance of selection. If the Committee's

recommendation be accepted, that grievance will be removed, for it has agreed "that pupils should be recruited for technical high schools at the age of 11 plus by means of the general selective examination by which pupils are at present recruited for the grammar schools".

That does not mean, however, that at the age of eleven years the curriculum will be what is called 'vocational'. Nor does it mean that, at any time during the course, it will be 'vocational' in its narrowest sense. Indeed, the Committee has been careful to guard in advance against the charge that its views may involve "the danger of premature specialization of a vocational character". It is pointed out, and in our view rightly, that much of the fear of vocationalism has arisen through misunderstanding and failure to define the term and to face the facts of educational development. The Committee underlines a point which had been made more than once in these columns : that, "in any subject worthy of inclusion in a school curriculum, it should be possible to lead the pupil to look beyond the immediate processes in which he is engaged to a wider human and social background"; and if that be not the path towards a really liberal and humane education, we confess that our own views stand in need of considerable revision. With that, and all its implications in mind, the Committee has recommended that the curriculum for pupils between the ages of eleven plus and thirteen plus in technical high schools should be broadly of the same character as the curriculum in other types of secondary schools of equal status. For pupils above the age of thirteen years the curriculum "should be designed so as to provide a liberal education with science and its applications as the core and inspiration".

Let there be no mistake : in making these recommendations the Committee has in mind certain junior technical schools and those alone. There are, under the general heading of schools providing technical education, trade schools, junior commercial schools, junior art departments and home training schools for girls. But, for reasons which the Committee examines with some care, and with which there will be a large measure of agreement, it is not prepared to say that such schools shall become technical high schools.

It may be, of course, that, just as some pupils after two years in a grammar school may be recognized as those who would gain the greatest educational benefit in a technical high school, there will be pupils of the latter who will be recognized as those who will profit most from the education of the grammar school. No system of education can be allowed to develop rigidity without diminution of its full possibilities. We are glad, therefore, to note that the Committee has recommended that there should be close relations between grammar schools and technical high schools, "so that the opportunity of transfer at about the age of 13 should exist for those pupils whose later development would be better suited by an alternative form of education".

Equality of status is further emphasized by a suggestion that the fees for technical high schools should be the same as those in grammar schools in the same administrative area. While fees exist, we believe that is a wise suggestion. We need not here go into the reasons for that belief. It is sufficient to say that there are still people who believe (and they are not altogether to be blamed) that the cost of an article is the truest indication of its value.

Hitherto, the junior technical school has perhaps owed a much larger measure of its success than is usually realized to its freedom from examinations. But, if equality is to be ensured, the present value placed by some upon the School Leaving Certificate is not to be neglected. In connexion with that certificate the Committee has expressed itself in terms discussed in *NATURE* of February 18. While, however, the Committee recommends that technical high schools should have some kind of school leaving certificate which will have general currency and bring before parents, employers and the public generally the fact that these schools are of equal status with the grammar schools, it guards, and very wisely in our view, against the imposition of a rigid external examination. Accordingly it

suggests an examination similar to the national certificate examinations, which have worked so well in senior technical colleges and which permit of internal examination with external assessment.

No one would deny that, if the fullest benefit is to be derived from the new technical high schools, their value should be made clear to all. "We find," says the report, "that there is much ignorance and misunderstanding of the aims, scope and work of the technical schools." The modern way of treating a defect of that kind is the way of publicity. The Committee does not shrink from that. "We think that education authorities might be well advised to give greater publicity to the aims and character of their technical schools, both to industry and to the general public. We have already indicated one or two reasons why the general public should know and appreciate more the work of these technical schools ; but there is at least one excellent reason for directing towards them the keener attention of industry."

That reason involves the question of apprenticeship, and we agree with the Committee that this should receive the immediate and earnest consideration of industry. The conditions of apprenticeship should be re-examined if only because there appears to be no uniformity of practice. Some firms will not accept a boy after the age of sixteen years. Some will do so, but insist that his apprenticeship should not end until five years after the date of his entry. Others will accept after sixteen years of age and will remit a period equivalent to that between the date of his sixteenth birthday and the date of his acceptance into industry. Others, still, will remit one year of apprenticeship to a boy who has satisfactorily completed a three-year course at an approved technical school. That, surely, is a position which needs alteration, and we feel with the Committee that it should be considered by employers' associations and by trade unions in order that a definite pronouncement of policy should be made. We do not think the Committee exaggerates when it says "a wise industrialist will be prepared and even eager to take as apprentices boys who have completed a technical school course at the age of 16 plus and should at least grant remission of that period between the sixteenth birthday and the date of actual commencement of apprenticeship, so that in all cases the apprenticeship would be completed on the twenty-first birthday."

It will be observed that, throughout what we have said, there have been no recommendations

affecting the senior technical colleges. That is to be expected, because the senior colleges did not come within the Committee's terms of reference. It may be noted here that the new technical high schools will, where possible, be housed in, and be departments of, technical colleges. The head master of the school will be the head of that department. Even where the school cannot be housed in the college, it is recommended that "its buildings should be linked with buildings of the college in order to facilitate participation in equipment and staff". The school, however, should have its own sub-committee of governors to whom the head master should have direct access.

We welcome the Committee's suggestion of the new technical high school not only because it is needed as part of a unified system of secondary

education, but also because it recognizes the liberal quality inherent in technical education, and, in doing so, it faces what it has itself called the facts of educational development. It recognizes the efforts which are being made to evolve a new type of secondary school "providing a liberal education, based on a more realistic and scientific curriculum than that of a grammar school", and in doing so it underlines a point which we have made more than once in these columns: that culture is not necessarily an unchanging quality, but something which may change with the progress of mankind. Perhaps, then, it is not too great an exaggeration to say that, behind the apparently sombre and shapeless civilization which we are making, there lies the possibility of a nobler culture than has yet been known.

Some Seventeenth Century Astronomers

Hevelius, Flamsteed and Halley :

Three Contemporary Astronomers and their Mutual Relations. By Eugene Fairfield MacPike. Pp. ix+140+4 plates. (London: Taylor and Francis, Ltd., 1937.) 12s. 6d. net.

IN this book the editor of the "Correspondence and Papers of Edmond Halley" has brought together brief, straightforward lives of the three great astronomers named in the title; a separate consideration of their commerce together and mutual relations; and, in appendices, several documents and letters concerning them, chiefly Hevelius. Where the pieces are in Latin a translation has in some, but not in all, cases been furnished by the pen of Mr. A. H. White.

This method of assembling the information set before the reader is not without its disadvantages, for it is bound to lead to either gaps or repetitions. Thus, in the life of Halley, only passing reference is made to the extremely important visit to Hevelius, when Halley tested telescopic sights against the open sights always used by the Danzig astronomer. This matter is dealt with at length in the joint consideration of the three astronomers, while the matter of the piracy, or call it what you will, of Flamsteed's observations is considered, with considerable repetition, in both the separate and the joint life. The book is, perhaps, rather a collection of valuable notes than balanced biography.

In his preface, the author refers to a manuscript autobiography of Flamsteed, preserved at

Greenwich, which he has used. This may account for the uneven style of the life, which is a mixture of the modern idiom and typical seventeenth century phrases, taken, we hazard, unchanged from the source, such as, for example, the following: "... lent him Sacrobosco's *Spheres*, in Latin, a work which, being perfectly suited to the natural turn of his genius, he perused with uncommon satisfaction", and elsewhere we find "dioptrics" and "Sir Clowdisley Shovell" used in the ordinary text. The life of Halley is much fuller than the others, in accord with the author's special interest. The quarrel between Flamsteed and Halley is discussed at some length, and put down to Flamsteed's jealousy, as in a sense it may have been, but Flamsteed was a man who had suffered many genuine wrongs, who had spent his scanty private means and all his energies freely in the service of astronomy and who had "endured long and painful distempers". Perhaps he was jealous of the genial, social, worldly and successful Halley, who must certainly have been a very much more entertaining companion, but it is a jealousy that may excite our pity rather than our scorn.

The book is of great interest to those concerned not only with the astronomers themselves but also with Hooke, for it was Hooke who in his "Animadversions on the first part of the *Machina Coelestis*" first insisted on the advantages of telescopic sights over open sights, and clearly explained the nature of optical resolution. The tests which Halley carried out at Danzig with telescopic sights and with the instruments of Hevelius frequently come

up for mention, and they are described at some length, with quotations from Halley's letter, in the part which deals with the mutual relations of the astronomers. Halley was surprised at the agreement which Hevelius could obtain with two different instruments, and implies that angles could be accurately measured to within five seconds with open sights, which seems astounding. He left a testimonial letter with Hevelius which exists in Olhoff's scarce collection, but is, unfortunately, not reprinted here. We could wish that these tests, and the whole question of the accuracy obtainable with the best open-sight instruments, might be discussed in more detail by a practical observer. That Halley could not do better with his telescopic sextant may have been due to a mechanical, as against an optical, inferiority of his instrument.

Halley himself, in spite of his favourable opinion of the observations of Hevelius, soon rallied, with the rest of the learned world, to Hooke's opinion, for while the Danzig visit took place in 1679, we find him writing to William Molyneux in 1686, "The controversy between Mr. Hevelius and Mr. Hook, as you very well observe does, as Hevelius manages the matter, affect all those observers that use Telescope sights, and myself in particular, and

it is our common concern to vindicate the truth from the aspersions of an old peevish gentleman, who would not have it believed that it is possible to do better than he has done". This kind of change of tone must be taken into account in considering Flamsteed's estimate of the character of Halley. Flamsteed, writing at about the same time, with the same views, does himself credit with the following generous sentiment: "Nor doe I find myselfe so far concerned in his writings as that I can thinke myselfe obliged to stand up in their defence at this time, hee [Hevelius] is very old, has obliged the World much by his labors, has taken a vast deal of paines and been at great cost to publish them, hee has suffered much of late and it would look like a piece of Inhumanity to vex him with an examination of his workes, under these circumstances".

Mr. MacPike's book is beautified with some excellent portraits, including one of Elisabeth Hevelius, surely the first recorded woman astronomer, the forerunner of Caroline Herschel and so many other illustrious ladies. It has an excellent index of names, and deserves a place on the shelves of students of the seventeenth century.

E. N. DA C. A.

Wild Flowers of Attica

Wild Flowers of Attica

By the late Shirley Clifford Atchley. Prepared for publication by Dr. W. B. Turrill. Pp. xix+60+22 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1938.) 25s. net.

MR. SHIRLEY ATCHLEY, long a member of the British Legation at Athens, was a man who published nothing, but enjoyed a scholar's reputation among men of learning. For he knew the paths and the by-paths, the beaten and unbeaten tracks of Greece as no one else did and probably no other man had ever done; and his knowledge was so great as to become almost legendary of the language and its dialects, the folklore and not least the field-botany, both of the mainland and of the islands. He dreamed of the books he should write some day; he even planned one on the vernacular names of the Greek plants, but nothing came of it. But he kept on sending plants, rare and common, to Kew until he built up a great herbarium, and the more his reputation grew the more kindly and good-humouredly did he answer the countless questions which men were wont to ask him.

The pretty book before us, based on his own

scanty notes and subscribed for as a keepsake by his friends, will so far serve its purpose, and keep in remembrance a learned, lovable and sweet-natured man. It is enriched and beautified by coloured drawings of some seventy or eighty flowering plants, the work of the author's friend and doubtless kindred spirit, Mr. W. O. Everett of Athens. There has been little or no selection here, for many of the plants figured are common familiar things; we feel even a little surprised to see *Cheiranthus Cheiri*, *Smilax aspera*, *Marrubium vulgare* and *Vinca major*, all faithfully portrayed. But after all, the book itself is no catalogue of rarities, and these common things do help somehow among the rest to suggest or recall the flower-carpet of Hellenic spring. The drawings are interesting in another way; for they look like the work of some old sixteenth-century herbalist, Brunfels perhaps, who knew little and cared nothing about the structure of the flower or even the precise outline of a leaf, but just gathered his plant, flowering or seeding, withered or green, and drew it exactly as it came. The mandrake on the frontispiece is a perfect drawing of its kind, and startlingly like this famous plant as one meets it growing by the wayside.

Beautiful as the book is, it saddens one to think how little is saved, how much is lost, of all the author's learning. There is little or nothing new or even strange to botanists and scholars in all these brief and sketchy annotations: even the vernacular names are few, and look odd in plain typography. Save only that a few are noted as Cretan names, there is nothing to show for what Atchley could alone have given us and what we should have so gratefully received, an account of the local plant names in provincial and insular Greece. The ancient name of 'mandragóras' still survives, says Atchley; but I should like to know whether he had ever heard it called γοργόκτυ as Unger found it many years ago. Of the forty or more Greek verbascums, only one is figured; we are merely told that "in various parts of Greece

species of *Verbascum* are used as fish-poisons", and, like some other poisonous plants, are called "phlómos": nothing more! Now Aristotle talks of the plant φλόμος as a fish-poison, and Aelian tells how it will rid our ponds of frogs; and Sibthorpe found one of the spurges so used and so called in his time; and Robert Walpole found it used by Albanian settlers at Salamis; and Heldreich found mullein and spurge and daphne and dog-mercury all called by the same name, and perhaps all used in the same way. We may take it for sure and certain that Shirley Atchley, and he alone, could have told us, precisely and adequately, the whole story, what species are used of this genus or of that, and where, and how—but now the rest is silence.

D'ARCY W. THOMPSON.

An Italian Psychologist

La psychologie expérimentale en Italie (École de Milan)

Par Dr. A. Manoil. (Bibliothèque de philosophie contemporaine.) Pp. viii+490+16 plates. (Paris: Félix Alcan, 1938.) 80 francs.

THIS book might well have been entitled "The Work of Agustino Gemelli", founder of the Catholic University of Milan and director of its Department of Psychology. As the following sketch of his life indicates, Prof. Gemelli is a remarkable man; in Dr. Manoil he has found a devoted and competent Boswell. After obtaining his doctorate at Pavia both in medicine and in science, he served for five years from 1898 as assistant to the histologist Golgi, carrying out research during this period on the hypophysis of the brain. But in 1903 he turned aside to theological studies and for four years led the life of a Franciscan monk. Then he resumed his scientific work, visiting between 1907 and 1911 the biological and neurological laboratories of Nussbaum and Verworn at Bonn and of Edinger at Frankfurt. In 1909 he promoted in Italy the neo-scholastic movement, which had also been introduced into the Catholic University of Louvain, the home of his distinguished colleague in experimental psychology, Prof. A. Michotte. In 1912 he obtained his doctorate in philosophy. Thereupon he began his career as an experimentalist psychologist, working in Germany at the psychological laboratories of Külpe and Kräpelin and carrying out research at the laboratory of Turin under Keesow. In 1916 he was at Munich studying 'psychological profiles' with reference to occupational selection. On the entry of Italy into the Great War, he joined her

army first as doctor and priest, later establishing the first psycho-physiological laboratory of the Italian army, for the study of aviation and the selection of airmen.

With this unique experience, Gemelli founded at Milan in 1921 the Catholic University of the Sacred Heart, which he provided with a large scientific library and with well-equipped biological and psychological laboratories. The latter laboratory he has since directed with remarkable energy, efficiency and versatility. For as Dr. Manoil rightly says, "there is virtually no field in theoretical, experimental or applied psychology which Prof. Gemelli has left untouched". In this volume he attempts to describe these manifold activities, both before the foundation of the Catholic University at Milan and, together with those of his colleagues and students, after its foundation. A bibliography of some 175 published papers is appended, of which by far the majority bear Prof. Gemelli's name. Some of those which are here described, generally in a historical setting, are to be found at full length in the six large volumes of *Contributi* from his laboratory which have appeared between the years 1925 and 1935.

The most important of these contributions relate to (a) the use of the psycho-physical method of 'equivalents' in the study of tactual illusions; (b) the elaboration, based on new experimental data, of a theory of perception; (c) electro-acoustic investigations of speech; and (d) the selection of air-pilots. The book also contains shorter chapters describing Prof. Gemelli's anatomical experiments concerning the psycho-physiological factors in emotion, his investigations in animal and industrial psychology, and his

applications of psychology to the problems of physical training. Throughout he insists on the 'finalistic principle', the 'purpose' in view, which directs the 'synthetic activity' of the subject.

Gemelli agrees with Michotte that in perception the fundamental and terminal factor is the apprehension of meaning—an intellectual act so closely bound up with the intuitive, sensorial organization of the data that they are usually only distinguishable under experimental conditions. Cinematographic investigations lead him and his colleagues to distinguish four degrees or phases in the developing perception of form and meaning—(i) of mere 'presence', (ii) of a 'form', (iii) of the apprehension of meaning, (iv) of identification by name. Other investigations are described into perception in peripheral and twilight vision, the perception of ambiguous profiles, etc. Throughout he is far from being a complete adherent to the Gestalt school, although he lays great stress on the function of the 'whole'.

Gemelli's experiments on speech (conducted with

his biologist colleague, Prof. Giuseppina Pastori) are based on an analysis of oscillograms, several of which are illustrated in fifteen plates. He insists that each unit—whether 'phonem' (the most elementary unit), word or sentence—is a whole; possessing an individuality which, however, is widely modifiable. Thus a phonem, especially a vowel, will be modified in the oscillogram according to accent, its situation in the word, and the nature of its neighbouring consonants; the vowel is influenced by the syllable, as the syllable is influenced by the word, the 'whole' being pre-existent in regard to the 'part' and determined by meaning and expression. Yet each phonem has a characteristic acoustic structure and an oscillographic form which gives it a specific and recognizable form.

These brief accounts must suffice to illustrate the broad field and the inevitably variable worth of Prof. Gemelli's labours. They deserve the international attention which they will receive by their publication in the present volume.

Birds of Sussex

A History of Sussex Birds

By John Walpole-Bond. Vol. 1 (Raven to Eastern Great Reed-Warbler). Pp. xix+382+12 plates. Vol. 2 (Reed-Warbler to Teal). Pp. vii+384+19 plates. Vol. 3 (American Blue-winged Teal and Red-legged Partridge). Pp. vii+384+22 plates. (London: H. F. and G. Witherby, Ltd., 1938.) 3 vols., £5 5s. net.

JOHN WALPOLE-BOND, a distinguished ornithologist of many years standing, in this his most recent work, in three volumes, has had the assistance as illustrator of Philip Rickman. Between them, author and artist (aided by that high standard of book production which is expected from the firm of Witherby) have produced a work which, it is safe to say, will rank as a standard one on Sussex birds.

The scope of the work can be realized when it is stated that more than four hundred bird species are dealt with. Of that number 112 nest regularly in the county.

Of the fifty-three coloured plates by Philip Rickman which nobly illustrate the work, the three which to some eyes are the most attractive are Montagu's harrier hunting, a shoveler duck and drake, and a male black redstart. The shovelers are portrayed with rare delicacy, and the harrier is shown moving above his feeding haunts; the graceful and buoyant, and yet somewhat furtive flight of the harrier has been caught with rare faithfulness by the artist.

The author in the compilation of this great work has laboured long and faithfully, and he has many interesting records of the birds of the county. He tells us that the raven no longer nests in Sussex although it still visits the Sussex coast on migration. The peregrine falcon, fierce pirate of the skies, still nests on the less accessible cliffs, the hobby still rears her young in the native woods, and in comparatively recent years a pair of Montagu's harriers nested in the county. Mr. Walpole-Bond does not say whether these birds succeeded in hatching their second clutch—the first was taken—but presumably he did all in his power to see that these rare eggs escaped the collector.

The peregrine is, it is interesting to learn, a bird which sometimes nests so near to villages that the rubbish from the dust-bin chute almost sprays the eggs:

The eyrie was—for the site has long since crumbled away, as chalk often will—only some fifteen feet down the steep on a long, broad bench which culminated in the chute down which the dust-bin refuse from the adjoining village was shot once a week; and the eggs were habitually laid only a foot or two from the chute itself. On this ledge could always be seen every conceivable sort of rubbish and in 1905 in the eyrie itself, and almost touching its contents, reposed an oblong strip of cardboard (Vol. II, p. 247.)

Of the supposed aerial climb of the swift into the sky of a summer evening he has something to say. It has been suggested by some ornithologists

that the swifts on occasion spend the night in the air, sleeping lightly as they soar at great heights above the earth. But Mr. Walpole-Bond, from many nocturnal vigils in the Horsham belfry, is convinced that swifts do return to roost after this evening flight to high altitudes. He has seen some of the merry-makers rush home at about 10 p.m. G.M.T., but all the birds were not home until after midnight—that is 1 a.m. by British Summer Time. These valuable observations show that the eyesight of swifts must be extremely good, as the bird must make an entry, flying at full speed, into its narrow nesting hollow during the darkest hour of the summer night.

In his chapter on the swift Mr. Walpole-Bond mentions the astonishing pertinacity of life in a click beetle. The author was handling a juvenile swift which in its agitation disgorged a click beetle. In two hours the limp, moist 'corpsé' had completely revived, although it had been caught in the mouth of the parent swift and had perhaps been carried a considerable distance, and had then been given to, and swallowed by, the young swift.

Writing of the autumn migration of the swift, the author mentions a single swift seen in Sussex on October 28, 1906. This calls to the reviewer's mind that he and his wife watched for some time a pair of swifts flying backwards and forwards over the leafless birches at Aviemore on the Spey Valley in Inverness-shire, where the river bed is 700 ft. above the level of the sea, on November 11 of a recent year. That day was unusually mild, yet the Cairngorm Hills were already thickly coated with their winter snowfall, and there was severe frost a few days before, and again almost immediately after, these wandering swifts were seen. Whence they had come, and how they had survived the frost was unknown, and we sometimes wondered whether their subsequent migration south had been successful.

It has of course been proved that swifts do on occasion become torpid in their nesting hollows in spring if severe weather should catch them after their arrival at their nesting haunts, but so far as is known, there is no record of their having been found in this condition in autumn. S. G.

Chemistry of the Brain

Chemistry of the Brain

By Dr. Irvine H. Page. Pp. xvii+444. (London: Baillière, Tindall and Cox, 1937.) 34s.

INTEREST in the biochemistry and physiology of the nervous system is increasingly being taken, not only by purely scientific investigators, but also by clinicians, psychiatrists and many of those who come into contact with the abnormal manifestations of the nervous system. Dr. Page's book has an appeal to all such workers, and presents a real stimulus to those for whom mental activity—normal and otherwise—is associated with the dynamic equilibria taking place in the brain.

The book commences with a brief biography of Thudicum, "the founder of brain chemistry". It passes on to a survey of our present knowledge of the sterols, the importance of which in the make-up of the brain is well known but of the significance of which in brain metabolism we are as yet ignorant. The chemistry of the phosphatides is next considered, and then Dr. Page turns to such subjects as fatty acid metabolism, cerebroside, carbohydrates and nitrogenous metabolism. The subjects are dealt with briefly but sufficiently adequately to present the most significant findings to a clinical research worker and to those whose main interest is the study of the brain.

There are omissions, and in places the subject-matter is out of date; but this is inevitable in a book which does not pretend to be a text-book of biochemistry and in a subject where advances are made so rapidly. Wherever possible Dr. Page keeps the clinical aspects well to the foreground, and one of the most valuable features of the book is the description of clinical findings in psychiatry and their possible interpretations in the light of our knowledge of the biochemistry of the nervous system. Effects of oxygen deprivation, of alterations in calcium ion concentration, of deprivation of magnesium and manganese, of the action of narcotics and drugs are a few of the many subjects which are considered. There is a brief survey of the parts played by the vitamins in maintaining the integrity of the nervous system, and the penultimate chapter (by Dr. J. H. Quastel) is devoted to a description of oxidations of the brain with a very brief survey of the present (that is, until 1936) situation concerning oxidations in the living cell.

References to original articles—clinical and otherwise—are copious. Much information is present which is not elsewhere readily available, and the book is a boon to biochemical and physiological workers in the psychiatric domain.

The book is well produced, but there is a fair number of misprints and incorrect formulæ.

Introduction to Bessel Functions

By F. Bowman. Pp. x+135. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1938.) 10s. 6d. net.

THIS book is designed to provide a readable introduction to the subject for non-mathematical specialists. Beginning with functions of zero order, the author sets forth in a clear and straightforward manner the solutions of Bessel's equation of zero order. The student is thus introduced not only to $J_0(x)$, but to Neumann's Bessel function of the second kind of zero order, and this leads to the general solution. The properties of the functions are then considered as far as the use of the Fourier-Bessel expansion, and some valuable illustrations of their application are made to the vibrating membrane and the hanging chain.

The modified function of zero order is next discussed and well applied to the flow of an alternating current in a wire of circular cross-section. Then follows a brief consideration of the simplest definite integrals involving $J_0(x)$, such as those of Parseval, Liapchitz and Weber, which are applied to the problem of the electrostatic potential of an electrified disk. The next chapter is devoted to asymptotic expansion with as much relevant theory as is essential to an intelligent understanding of the need for such expansion. Finally comes a clear, though brief consideration of the Bessel functions of any real order with an exposition of their chief properties. This is followed by some interesting applications, including Kepler's problem, the critical length of a thin uniform elastic rod clamped vertically and the normal modes of vibration of a circular membrane with its circumference fixed.

Each section contains some well-chosen exercises for the student's use and there is a useful index. The book is excellently printed with some clear diagrams, and should certainly prove very useful not only to students of physics and engineering, but also to mathematical students in general. F. G. W. B.

Plant Growth-Substances:

their Chemistry and Applications, with Special Reference to Synthetics. By Hugh Nicol. Pp. xii+108+4 plates. (London: Leonard Hill, Ltd., 1938.) 3s. 6d.

PLANT growth-promoting substances are now becoming of increasing importance not only to the research physiologist but also to the practical horticulturist. It has been the topic of international conferences and of discussions held at the Royal Botanic Gardens, Kew, and elsewhere.

Though full of information of value to the research worker, Dr. Nicol's book will prove of even greater value to the professional horticulturist. The subject-matter is based on a series of articles published in the *Manufacturing Chemist*. The following subjects dealt with in the book will appeal to students: synthesis of growth substances; results of work on the effect of such substances; growth-substances from natural sources; some constituents of urine; chemistry in relation to growth; classification,

nomenclature and identification of growth substances. The practising horticulturist will find these well-written chapters of interest and value also, and he is offered still further help in the first two chapters. The tabular index at the end is very useful.

Dr. Nicol is to be congratulated on a very useful book which his publishers have issued at a reasonable price. It can be strongly recommended to students of, and research workers in, plant physiology, and to the horticulturist who is alive to the opportunities which scientific research is offering him to his advantage.

Cataloguing in Special Libraries:

a Survey of Methods. By John L. Thornton. Pp. xii+268. (London: Grafton and Co., 1938.) 10s. 6d. net.

THIS book, by the assistant librarian of St. Bartholomew's Hospital, will interest all librarians who have charge of special collections. It is an investigation of the cataloguing methods used in various types of special library—national, government, university, learned society, commercial, technical and school—with examples of how their special difficulties are met. Representative libraries of each type are dealt with in detail. In addition there are chapters on alphabetization, treatment of serial publications and co-operative cataloguing.

The survey reveals a great diversity of cataloguing systems and a great shortage of cataloguing staff. Mr. Thornton's comments are shrewd and at times outspoken. He does not, happily, belong to the school which aims at transforming librarianship from a useful art to an arcane science. His style is clear, concise and free from jargon, and he keeps the library user always in the foreground. The book is illustrated with specimen card and other catalogue entries. Except for some minor details, it is well produced and printed. B. S.

Varieties of British Butterflies:

a Selection of Rare and Interesting Specimens of Aberrations, including Gynandromorphic and Homoeotic Forms; Albinism and Melanism. By F. W. Frohawk. Pp. 200 (48 plates). (London and Melbourne: Ward, Lock and Co., Ltd., 1938.) 42s. net.

MR. FROHAWK'S object is apparently to figure rare and interesting varieties and other unusual forms, including gynandromorphs, of British butterflies. In so far as this object is concerned, the task has been well carried out. Mr. Frohawk is a highly skilled entomological artist and the forty-eight colour plates illustrating this book bear ample testimony to his artistic ability. Abnormal forms of butterflies have, in recent years, become highly prized by collectors and consequently fetch considerable prices at auction sales. For the collector, therefore, this work is certainly admirable. We regret that a book so highly priced should contain very little scientific information on the subject treated. The real student who desires to know something regarding modern views as to the underlying causes producing the remarkable 'forms' will have to go elsewhere for information.

Cause, Purpose and Economy of Natural Laws*

Minimum Principles in Physics

By Prof. Max Born

WITHOUT claiming to be a classical scholar, I think that the earliest reference in literature to the problems which I wish to treat here is contained in Virgil's "Aeneid", Book I, line 369, in the words "taurino quantum possent circumdare tergo."

When Dido landed at the site of the citadel of Carthage, she opened negotiations with the inhabitants for some land and was offered for her money only as much as she could surround with a bull's hide. But the astute woman cut the bull's hide into narrow strips, joined them end-to-end and with this long string encompassed a considerable piece of land, the nucleus of her kingdom. To do this she had evidently to solve a mathematical question—the celebrated 'problem of Dido': to find a closed curve of given circumference having maximum area. We do not know how she solved it, by trial, by reasoning, or by intuition. In any event, the correct answer is not difficult to guess: it is the circle. But the mathematical proof of this fact has only been attained by modern mathematical methods.

In saying that the first appearance of this kind of problem in literature is that quoted above I am not, of course, suggesting that problems of minima and maxima had never occurred before in the life of mankind. In fact, nearly every application of reason to a definite practical purpose is more or less an attempt to solve such a problem: to get the greatest effect from a given effort, or, putting it the other way round, to get a desired effect with the smallest effort. We see from this double formulation of the same problem that there is no essential distinction between maximum and minimum; we can speak shortly of an 'extremum', and 'extremal' problems.

It was during Isaac Newton's lifetime, at the end of the seventeenth century, that geometrical and mechanical problems of extremals began to interest mathematicians, and shortly after Newton's death (1727) the metaphysical idea of purpose or economy in Nature was linked up with them.

One of the simplest examples is the optical 'law of reflection' which can be expressed as a minimum principle: the beam of light from a point P_1 to another point P_2 selects just that reflecting point Q which makes the total path

$P_1Q + QP_2$ as short as possible. The light behaves as if each beam had a tendency to contract, and the French philosopher, Fermat, has shown that all the laws of geometrical optics can be reduced to the same principle. Light moves like a tired messenger boy who has to reach definite destinations and carefully chooses the shortest way possible. Are we to consider this interpretation as accidental, or are we to see in it a deeper metaphysical significance? Before we can form a judgment, we must learn more about the facts and consider other cases.

The straight line is the shortest connexion between two points in space. But if we travel on our earth, we can never go exactly in a straight line since the earth's surface is not plane. The best we can do is to follow a great circle, which is the curve in which the sphere is intersected by a plane passing through the centre. The globe, however, is not an exact sphere, but is slightly flattened at the poles and bulges at the equator. What, then, about the shortest line on such a surface?

Gauss hit on this problem when occupied with a geodetic triangulation of his country, the electorate of Hanover. He attacked the problem from the most general point of view and investigated the shortest lines on arbitrary surfaces. But in remembrance of his starting point he called these lines 'geodesics'. They are in many ways of fundamental importance for physics.

Let us consider a point P on a surface and all curves through P which have the same direction at P . It is evident that there is among them a 'straightest curve', that is, one with the smallest curvature. Hence the geodesic can be characterized by two somewhat different minimum properties: one which can be called a 'local' or 'differential' property, namely, to be as little curved as possible at a given point for a given direction; and the other, which can be called 'total' or 'integral', namely, to be the shortest path between two points on the surface.

This dualism between 'local' and 'total' laws appears not only in this simple geometrical problem, but also has a much wider application in physics. It lies at the root of the old controversy whether forces act directly at a distance (as assumed in Newton's theory of gravitation and the older forms of the electric and magnetic

* Substance of the Friday evening discourse delivered at the Royal Institution on February 10.

Fig. 1.

theories), or whether they act only from point to point (as in Faraday's and Maxwell's theory of electromagnetism and all modern field theories).

There seems to be no objection to extremal laws of the local type; but those of the integral type make our modern mind feel uneasy: although we understand that the particle may choose at a given instant to proceed on the straightest path, we cannot see how it can quickly compare all possible motions to a distant position and choose the shortest one—this sounds altogether too metaphysical.

But before we follow out this line of thought, we must convince ourselves that minimum properties appear in all parts of physics, and that they are not only correct but also very useful and suggestive formulations of physical laws.

One field in which a minimum principle is of unquestionable utility is statics, the doctrine of the equilibrium of all kinds of systems under any forces. The centre of gravity tends to descend as far as possible; to find the configuration of stable equilibrium, one has only to look for the minimum of the height of the centre of gravity. This height, multiplied by the force of gravity, is called potential energy.

A chain hanging from both ends assumes a definite shape, which is determined by the condition that the height of the centre of gravity is a minimum. If the chain has very many links, we get a curve called the catenary. It can readily be shown by means of a heavy chain, the centre of gravity of which is marked by a construction,

of light levers, that disturbance of the equilibrium of the chain in any arbitrary way causes the centre of gravity of the chain to rise.

Fig. 1 illustrates an example where gravity competes with another force, elasticity. A steel tape is clamped at one end and carries a weight at the other. This weight is pulled downwards by gravity, while the tape tries to resist bending in virtue of its elasticity. This elastic force also has a potential energy; for a definite amount of work must be done to bend the tape into a given curved shape. Now there are definite positions of equilibrium in which the total energy, that of gravitation plus that of elasticity, is as small as possible. Generally there are two such positions. Changing the clamping angle carefully, a position is found when a jump suddenly occurs from one position to another on the opposite side. This instability is determined by the condition of minimum energy. We can summarize the facts connected with the limits of stability by drawing a graph, Fig. 2, not of the elastic lines themselves, but by plotting the angle of inclination against the distance from the free end. We obtain wave-shaped curves, all starting horizontally from the line representing the end carrying the weight. These curves have an envelope which separates the regions in which one or several curves are going through each point, and calculation shows that this envelope is just the limit of stability. We shall return to this example later when discussing the minimum principles of dynamics.

Fig. 2.

Another example of the statical principle of minimum energy is provided by soap bubbles. Soap films have the property of contracting as much as possible; the potential energy is proportional to the surface area. Therefore soap films are surfaces of smallest area, or minimal surfaces. Nature is an expert mathematician, quickly finding the solution.

These experiments are not merely pretty toys without serious background. They have been chosen only for the sake of illustration. The real importance of the principle of minimum energy can scarcely be exaggerated. All engineering constructions are based on it, and also all structural problems in physics and chemistry.

Models of crystal lattices provide examples of this. A crystal is a regular arrangement of atoms of definite kinds in space. Now the models representing the crystal lattices of two chemically similar compounds, namely, common salt (NaCl) and caesium chloride (CsCl) are different in structure. Why are they different? Because, as the caesium atoms are much larger than the sodium atoms, the potential energy differs in the two cases and its minimum is attained for different configurations.

Considerations of this kind, more or less quantitative, enable us to understand a great number of facts about the internal structure of solid matter.

Before we proceed to the consideration of minimum principles in dynamics, where the situation is not as clear and satisfactory as in statics, we must first mention another part of physics which in a sense occupies an intermediate position between statics and dynamics. It is the theory of heat, thermodynamics and statistical mechanics.

There is a very important extremum principle, discovered by Lord Kelvin, which governs irreversible processes: a quantity called 'entropy' increases in the process and has a maximum for the final equilibrium state. It is not easy to describe this miraculous entropy in terms of directly observable quantities, such as volume, pressure, temperature, concentration, heat. But its meaning is immediately obvious from the point of view of atomic theory. A model will facilitate the explanation. Take a flat box like a little billiard table into which marbles can be put. If I carefully place them in the right-hand half, I have a state of partial order; if I shake the box they spread out over the whole box and attain a configuration of lower order. If I throw some marbles into the box one after the other so that their position is purely accidental, it is very improbable that they will all fall in the right-hand half. One can easily calculate the probability of a uniform distribution over the whole box as compared with one in which the majority of the marbles is in the right half;

and one finds overwhelming odds in favour of the uniform distribution. Now the statistical theory of heat interprets the entropy of a system with the aid of the probability of the distribution of the atoms, and the tendency of entropy to increase is explained by the obvious fact that states of higher disorder have a higher probability.

Let us now come back to the minimum principles of dynamics.

The first problem of this kind—first both in historical order and in order of simplicity—was formulated at the end of the seventeenth century by Johann Bernoulli of Basle, one of a great family which produced many famous scholars and especially mathematicians. It is the problem of the curve of quickest descent or brachistochrone: given two points at different levels, not in the same vertical line, to determine a connecting curve in such a way that the time taken by a body to slide without friction under the action of gravity from the higher point to the lower is a minimum—compared of course with all possible curves through the two points. With a model having three paths, namely, a straight line, an arc of a circle and an intermediate curve known as a cycloid, it can be shown that it is not the straight line on which a rolling ball arrives first, nor the steep descent of the circular arc, but the cycloid. If you were to try with any other curves, you would always find the same result, for the cycloid has been constructed according to the theoretical calculation.

The determination of this brachistochronic property of the cycloid was a very satisfactory piece of mathematics. It attracted much attention, and there is no philosopher of this period who did not test his analytical powers by solving similar extremal problems. Another member of the Bernoulli family, Daniel Bernoulli, developed at the beginning of the eighteenth century the minimum principle of statics and applied it to the catenary and the elastic line. Encouraged by these successes, he raised the question whether it was possible to characterize the orbit, and even the motion in the orbit, of a body subject to given forces—for example, a planet—by a minimum property of the real motion as compared with all other imagined or virtual motions. He put this question to the foremost mathematician of his time, Leonard Euler, who was very much interested in it and found, in the autumn of 1743, a solution which he explained with the help of various examples in a book published in 1744. It is the basis of the *principle of least action* which has played so prominent a part in physics right up to the present time.

The history of this principle, however, is an amazing tangle of controversies, quarrels over

priority and other unpleasant matters. Maupertuis, in the same year, 1744, presented a paper to the Paris Academy of Sciences in which he substituted for Fermat's optical principle of the shortest light path, which we have already discussed, a rather arbitrary hypothesis, and extended the latter, in 1746, to all kinds of motions. He never gave a satisfactory proof of his principle (which is not surprising as it is incorrect), but defended it by metaphysical arguments based on the economy of Nature. He was violently attacked by Chevalier d'Arocy in Paris, Samuel König from Bern and others, who showed that if Maupertuis's principle were true, thrifty Nature would be forced in certain circumstances to spend not a minimum but a maximum of action! Euler, whose principle is quite correct, behaved rather strangely; he did not claim his own rights, but even expressed his admiration for Maupertuis's principle, which he declared to be more general. The reasons for this attitude are difficult to trace. One of them seems to have been the publication by König of a fragment of an alleged letter of Leibniz in which the principle was enunciated. The genuineness of this letter could never be proved, and it seems probable that it was a forgery designed to weaken Maupertuis's position. This may have brought Euler over to the side of Maupertuis, who was at this time president of the Berlin Academy and a special favourite of the king, Frederic II, later known as the Great. The dispute was now carried over into the sphere of the court of Sanssouci and even into the arena of politics. Voltaire, friend of Frederic, who heartily disliked the haughty president of the Academy, took the side of the 'underdog', König, and wrote a caustic pamphlet, "Dr. Akakia", against Maupertuis. But the king, although he thoroughly enjoyed Voltaire's witty satire, could not sacrifice his grand president and was compelled to defend Maupertuis. This led at last to the disruption of their friendship and to Voltaire's flight from Berlin, as described in many biographies of Frederic and of Voltaire.

The curse of confusion has rested for a long period on the principle of least action. Lagrange, whose work was the culmination of the development of Newton's dynamics, gives an unsatisfactory formulation of the principle. Jacobi restricts it in such a way that the minimum condition determines the orbit correctly; the motion in the orbit must be found with the help of the energy equation. This was an important step. But the spell was at last broken by the great Irishman, Sir William Rowan Hamilton, whose principle is mathematically absolutely correct, simple and general. At the same time, it put an end to the interpretation of the principle expressing the economy of Nature. For there is,

by a kind of fortunate mathematical coincidence, a statical problem for which the statical minimum principle for the potential energy coincides formally with Hamilton's principle of least action for the pendulum; this statical problem is the loaded steel tape considered before. The curves representing the angle of inclination of the elastic line as a function of the distance from the free end are exactly the same lines as those representing the angle of deflection of the pendulum as a function of time (see Fig. 2).

Now we have seen that only those regions of the graph which are simply covered by the lines correspond to a real minimum, a stable configuration of the elastic line. There are other regions, those beyond the envelope, where two or more lines pass through a given point. Only one of those lines corresponds to a real minimum. But both represent possible motions of the pendulum. Although the conditions at the ends of the elastic tape do not correspond exactly to those at the ends of the time interval in Hamilton's principle, there is this fact in common: if the length of the tape or the corresponding time interval in Hamilton's principle for the pendulum exceed a certain limit, there is more than one possible solution, and not each of them can correspond to a true minimum, though to a possible motion. In this way we come to the conclusion that the actual motion is not in every case distinguished by a genuine extremal property of action but by a less obvious mathematical property called 'stationary' configuration.

Thus the interpretation in terms of economy breaks down. We may regard the idea of finding purpose and economy in natural laws as an absurd piece of anthropomorphism, a relic of a time when metaphysical thinking dominated science.

The importance of Hamilton's principle lies in a different direction altogether. It is not Nature that is economical, but science. All our knowledge starts with collecting facts; but proceeds by summarizing numerous facts by simple laws and these again by more general laws. This process is very obvious in physics. We may recall, for example, Maxwell's electromagnetic theory of light, by which optics became a branch of general electrodynamics. The minimum principles are a very powerful means to this end of unification. The ideal would be to condense all laws into a single law, a universal formula, the existence of which was postulated more than a century ago by the great French astronomer, Laplace.

If we follow the Viennese philosopher, Ernst Mach, we must consider economy of thought as the only justification of science. I do not share this view—there are other aspects and justifications of science. But I do not deny that economy

of thought and condensation of the results are very important, and I consider Laplace's universal formula as a legitimate ideal. There is no question that the Hamiltonian principle is the adequate formulation of this tendency. It would be the universal formula if only the correct expressions for the potential energy of all forces were known. Nineteenth century thinkers believed more or less explicitly in this programme, and it was successful in an amazing degree.

By choosing a proper expression for the potential energy, nearly all phenomena could be described, including not only the dynamics of rigid and elastic bodies, but also that of fluids and gases, as well as electricity and magnetism, together with electronics and optics. The culmination of this development was Einstein's theory of relativity, by which the abstract principle of action regained a simple geometrical interpretation. The motions of the planets can be considered as 'geodesics' in the four-dimensional space formed by adding time to our common space. Einstein's law of gravitation, which contains Newton's law as a limiting case, can also be derived from an

extremum principle in which the quantity that is an extremum can be interpreted as the total curvature of the space-time world.

We call this period of physics which ends with the theory of relativity the classical period, in contrast to the recent period which is dominated by quantum theory. The new quantum mechanics assumes that all laws of physics are of statistical character. The fundamental quantity is a wave function which obeys laws similar to those of an acoustical or optical wave; it is not, however, an observable quantity, but determines indirectly the probability of observable processes. The point which interests us here is the fact that even this abstract wave function of quantum mechanics satisfies an extremum principle of the Hamiltonian type.

We are still far from knowing Laplace's universal formula, but we may be convinced that it will have the form of an extremal principle, not because Nature has a will or purpose or economy, but because the mechanism of our thinking has no other way of condensing a complicated structure of laws into a short expression.

Science at the Golden Gate Exposition

By Science Service, Washington, D.C.

A SUPER-SPECTACLE of science at work is unfolded at the Golden Gate International Exposition, the World's Fair of the West, at San Francisco, which was opened on February 19. Treasure Island itself is an engineering triumph, for it is entirely a man-made island in San Francisco Bay, 400 acres in area. After the close of the fair, the buildings will be razed and the island will become the San Francisco-Bay Area airport; already Pan-American Airways Clippers to the Orient use the island as the home port. From the hunt for subatomic particle of tiniest size to wondering about the course of a distant star, from war on death-dealing virus too small to be seen under an ordinary microscope to giant engineering projects like man-made Treasure Island itself, science dominates the 50,000,000 dollar show.

Only one hall bears the identifying label, "Hall of Science", but the entire exposition is as much a demonstration of the research worker's genius and accomplishments as this single building. Student of biology or of physics, layman or lover of the spectacular—all will find what they want in this twentieth-century panorama. Rats are thriving on synthetic food, insect friend of man battles insect foe, two liquids become artificial rubber, a machine

talks in words that never issued from a human throat—all this happens and much more during the 288 days the fair will be open.

The keynote of the entire science display is an exhibit which cost a quarter of a million dollars, prepared by the University of California. Among the exhibits of particular scientific interest are the following. (a) 'Test tube' plants, grown by scientific workers of the Plant Nutrition Division of the University of California in a demonstration of the most significant contribution of agricultural science to modern farming—'soilless farming'. Just as Pan-American Airways is doing on tiny Wake Island to supply fresh vegetables to clipper passengers and crews and as California planters are now learning, tomatoes and other truck products are grown in water containing nourishing chemicals instead of in soil. Spectators will see for themselves the tremendous yields made possible by this method. (b) Californian men of science show in a specially constructed chamber just how harmful noise can be to the human organism, and what can be done about it. (c) No playthings are a set of dolls which are displayed. They teach the curious thousands how mother and father pass on their characteristics to their

[Science Service]

FIG. 1. A GENERAL VIEW OF TREASURE ISLAND, SITE OF THE GOLDEN GATE INTERNATIONAL EXPOSITION, AND THE EXPOSITION BUILDINGS.

children. Colour of eyes is the specific characteristic traced in the set of exhibition mannequins. (d) The University of California, where Prof. Ernest O. Lawrence, of cyclotron fame, is a faculty member, is a world centre of research into the secrets of the atom. So it is to be expected that a model of the world's and California's greatest cyclotron should be there.

California's biggest academic institution, however, is not the only science exhibitor. Pan-American Airways is staging a great aviation show by demonstrating the operation of the clippers that fly to China and the Philippines. Small boys face plenty of competition from their elders for space behind the glass partition in Pan-American Airways' great new hangar. On the other side, 'grease monkeys' and members of crew and passengers go about their business. Treasure Island has become the new San Francisco base for the airline that flies the Pacific, and all operations will be visible for the duration of the Fair. After December 2, closing day, and after the exhibit buildings have been removed, other airlines will transfer their headquarters from Oakland Airport and Mills Field on the San Francisco side of the bay to this single skyport.

Riches of the earth and the miner's art are shown in a synthetic mountain, Treasure

Mountain, which visitors enter through a 'valley' between two 'mountain ranges'. Every type of mining operation on different key ores of the mineral-laden West is shown in working form—a 2,500-miles science trip in a few minutes. The peak is 50 ft. high and 400 ft. long.

Anthropologists and archaeologists will find assembled unbelievably old treasures, dating back to earliest times, from the countries bordering the Pacific. Stone axe heads forty-nine centuries old from Siam, and gorgeous specimens of the goldsmith's art in the Chimu culture that preceded Peru's highly civilized Incas of four hundred years ago, that have added to man's store of knowledge concerning himself, are shown on Treasure Island.

The Federal exhibit, which cost one and a half million dollars, shows activities of the National

[Science Service]

FIG. 2. TREASURE ISLAND JUST BEFORE BUILDINGS, TREES, SHRUBS AND FLOWERS AND EXHIBITS BEGAN TO BE MOVED ON TO THE ISLAND.

Government, as they affect citizens, around seven central themes. One, for example, displays in dramatic form what Uncle Sam does for Mr. Average Man from birth through old age—how, for example, Public Health Service grants provide better maternity care and how the Social Security Board now provides for a man in his declining years.

Indians demonstrate their handicrafts in the Federal building. Not only do they show their unique art, but also they may start a vogue for Indian handicrafts among visitors. Planners of the exhibit certainly hope so, for such a boom would prove a boon to the Red man, who has not had an easy row to hoe in adapting himself to the white man's civilization.

Chemical wizardry, as practised by industrial giants whose ever-new products enter into everyone's life every day, are also shown. The Dow Chemical Company shows how it makes ocean water yield up magnesium, the lightest metal now in use, and iodine and bromine, two vital chemicals which enter into, among other things,

the old stand-by antiseptic and photographic film respectively.

A chemist pours the clear contents of one beaker into another and a gummy substance, which is then moulded into proper shape, results. It is allowed to solidify, and, lo! a rubber tyre. How chemistry makes for better living in this and in other ways is shown by E. I. du Pont de Nemours and Co.

An 'iron lung', about which much has been heard recently and which has saved many lives, is there. Visitors have a chance to watch one at work in a model hospital erected by Dr. Gabriel Barnett.

In charge of the vast science programme in the Hall of Science alone has been Dr. Milton Silverman. Co-operating with him as exhibitors he has had some of the foremost scientific institutions in the United States. Harvard University, the Mayo Clinic, the Jackson Clinic and the American Medical Association, to mention only a few, are taking part. More than two hundred and fifty industrial exhibits, of which many are science shows all by themselves, are represented.

Technical Education in Great Britain

AS was to be expected, the principal discussion at the annual meeting, held in London on February 24-25, of the Association of Technical Institutions, centred around the recommendations with regard to technical education put forward in the Spens Report. Sir Henry Steward, chairman of the City and Guilds of London Institute, who has succeeded Sir Robert Pickard as chairman of the Association, presided over the meetings, which were held in the Hall of the Merchant Taylors Company.

The discussion was opened by Principal J. Paley Yorke, one of the signatories to the Report, and chairman of the Council of the Association. He said that the general trend of the Report has been aptly expressed by one commentator as "a shifting of the basis of education from one of *social habit* to one of *natural aptitude*". Who should say that a parent should not take account of the social implications which attach themselves to a child by attendance at one school or another? But if some equality of status can be secured between schools of different educational types the parent will no longer find himself forced to weigh social esteem against educational provision. He need only think of the fitness of the curriculum for the aptitude and the inclinations of the child. The text of the Report on the inside title-page is "Chacun doit être à portée de recevoir l'éducation qui lui est propre." The recommendations endeavour to make that possible.

Mr. Paley Yorke then went on to describe and explain the findings of the Committee set out in Chapter viii—"Technical High Schools and other Technical Schools". He pointed out that the terms of reference made it necessary for the Committee to give a detailed consideration of the aims, objects and work of those schools called Junior Technical Schools and to determine their actual and potential relation to secondary schools of other types. This is the first time in history that so complete an examination has been made by so important a Committee. The members of the Committee found it necessary to collect a large body of evidence, and they visited a number of representative schools to obtain for themselves a true picture of their work, of the staffing, equipment and corporate life. The Committee was greatly impressed through these visits and was the better able to assess the oral and written evidence received. It recognized that there are two main groups of Junior Technical Schools in existence—one frankly and definitely preparing its pupils for entry into a specific occupation and developing in them a substantial measure of personal skill in the processes of that occupation—the other providing an educational foundation and background with science and its applications as the core and inspiration of the curriculum for those whose broad intention it is to enter industry without reference to any particular occupation within it. It came to the very definite conclusion that the schools of this second

group are capable of developing, and indeed already had developed in a large degree, a form of secondary education which ought to be regarded as an alternative to that of a Grammar School.

From this the Committee made its now famous recommendation that a new type of school should be established to be called a Technical High School—to be accorded in every respect equality of status with schools of the Grammar School type, yet to be wholly distinct from them. As a first step it was recommended that a number of these Junior Technical Schools at present providing a curriculum based on the engineering and building industries should be converted into Technical High Schools. The recommendation carried with it the provision of a minimum course of five years with a recruitment at 11 plus years, the recruitment based on the method of the general selective examination by which children are recruited for the Grammar Schools, the ultimate selection being determined in accordance with the choice of the parents, the report of the head of the contributing school and the result of interviews.

It was considered essential, of course, that the curriculum of the 11 plus to 13 plus pupils should be broadly of the same character as that in other secondary schools so that there could be another age point, *in all schools*, namely 13 plus, at which transfers should, if desirable, be made—equally for eliminating misfits, and for the encouraging of aptitudes which might have emerged and for allowing a change of choice on the part of the parents.

Several points emerged from the recommendations, and Mr. Paley Yorke made special reference to the question of the housing and staffing of the Technical High Schools, because he feels that there has been much misunderstanding about it and much non-understanding criticism from established secondary school quarters.

The Consultative Committee had no doubt whatever that the special value of the Technical High School depends upon its contact with the equipment and with the staff of a Technical College. The examples were before it. The evidence was there. The experiment has been conducted for more than thirty years with the 13 plus to 16 plus group, and there is no doubt at all about the results. Therefore it said that where possible Technical High Schools should be housed in the Technical Colleges and Technical Institutes and should be a department of the College, and the head master of the School would be head of that department. It is recognized, however, that the discipline, the corporate life and the general conduct of the school are necessarily distinct from those of the College, and that for these the head master should be responsible. It is also considered an *essential* feature of the Technical High School that it should

have some use of some of both the equipment and the staff of the College. Thus the head master of the School will have certain staff units wholly under his direction and will also have other members of the college staff working for him for a portion of their time, but who are not full-time members of the *school* staff. These teaching units will be attached to the College under the direction of one or other of the several heads of the departments of the College.

This organization of a Technical College into departments is not known in the secondary school world—and that accounts for the non-understanding of the essential condition that the principal of the College must secure and maintain the co-operation of the several heads of the specialized departments and their staffs, and the use of the laboratories, shops and special equipment, in the work and the life of the school.

There need be no fears about all this. It has been in operation for years and it is completely successful. The Committee is satisfied that—provided that a sub-committee of the Governing Body be appointed to manage the school and the head master has direct access to it, and the appointment of staff engaged exclusively in the work of the school be made in consultation with him—the organization of a Technical College through its principal and heads of departments allows a sufficient measure of autonomy to the head masters of the Technical High Schools whilst securing that vital contact of the School with the staff and equipment of the College which it regards as of primary importance.

Finally, in his review, Mr. Paley Yorke dealt with the vitally important recommendation of a form of school-leaving certificate based on internal examinations—assessed by approved assessors and endorsed by the Board of Education. As a body, the Association is familiar with certificates of this form through the now well-known and highly successful National Certificates and Diplomas. He is glad indeed that the Committee had been able to state so clearly that it does not seek to impose upon the Technical High Schools any system of external examination, with the necessarily rigid syllabus which would inevitably follow in its wake.

In the course of the subsequent discussion—a discussion which was carried over to the next morning—criticism came from those interested in education for commerce that the Committee has not recommended the establishment of Technical High Schools with a curriculum based on commercial education. Mr. Paley Yorke replied that the Committee had taken the view that, as at present constituted, the Junior Commercial Schools recruiting at 13 plus and 14 plus are more directly

comparable with those Junior Technical Schools preparing their pupils for entry to a specific occupation. Their usefulness and functions are not denied. He pointed out that this decision was based on the evidence received, but that though the door has at present been closed against their becoming Technical High Schools, it has not been locked or bolted; and indeed might be said to be

slightly ajar. In reply to other points raised, he pointed out that it was recommended that the word 'Junior' should be discontinued and that the official designation should be *Technical Schools* for the two and three-year course schools and *Technical High Schools* for the others; but it was also recommended that each school should have its own local name.

Obituary Notices

Prof. Karl Schröter

THE nector of Swiss botanists, Karl Schröter, emeritus professor in the Federal College of Technology, Zurich, died on February 7 in his eighty-fourth year. Up to the last he was physically and mentally active, and so recently as January 28 he delivered a public lecture to a leading scientific society in Zurich. Unfortunately, after a brief attack of pneumonia following upon influenza, his long and active life came to a sudden end.

Karl Schröter was born in 1855 in Esslingen in Germany, where his father was then chief engineer in a large engineering establishment, but later appointed professor of engineering in the Federal College of Technology, Zurich. At this institution, his son Karl, who acquired Swiss nationality, commenced his studies of natural science and came under the stimulating influence of Karl Cramer, who persuaded him to devote himself to the study of botany. Two years after graduation in 1876, he established himself as *Privat Dozent* and a few years later he was invited to give a course of advanced lectures in place of Prof. Heer, who was taken seriously ill. He proved himself to be such a successful lecturer that on the death of Prof. Heer he was appointed, at the age of twenty-eight years, to the vacant professorship, which he held for forty-two years.

Schröter had been influenced in his botanical studies by his predecessor, choosing for his doctor's thesis the examination of some fossil woods collected by Heer in the far north.

Schröter was, however, more interested in living plants, and as an assistant he took an active part in the organization of botanical excursions for the students, by which means he acquired a very wide and varied acquaintance with the Swiss flora, which characterized his later work both as a teacher and as an investigator. In 1889, he published a pocket-flora of alpine plants which was translated into both French and English. He was, however, specially interested in the relationship of plants to their surroundings, and thus was one of the founders of the modern study of ecological botany. After many years work on alpine meadows and moorlands, he published, with the assistance of other botanists, in six parts during the years 1904-8 his "Plant-life in the Alps", a very comprehensive study of alpine vegetation. At the same time, he was collaborating

with J. Früh in the production of a monumental volume on the bogs of Switzerland. He did not, however, confine himself to flowering plants, but paid attention to the plankton flora of the Swiss lakes and published several accounts of the periodicity of some of its algal forms.

In 1898, Schröter undertook a journey around the world, visiting the United States, Honolulu, Japan and Java. The result of his trip made him an enthusiastic supporter of the movement to organize international phytogeographical excursions, and in connexion with these he visited both Great Britain and the United States. Though already ageing in 1923, he organized and led a party of plant geographers through the Swiss Alps. By that time, the Swiss National Park had been established in the Lower Engadine, and Schröter, who had been keenly interested and active in its establishment and had taken part in its botanical exploration, naturally included it in the itinerary of the excursion.

Schröter's many-sided botanical labours received due recognition both in Switzerland and abroad. He was elected a foreign member of the Linnean Society of London in 1925 and delivered the Hooker Lecture of the Society in 1926. His lively and charming personality gained him many friends at home and abroad, not a few in England, which he visited on several occasions.

He married in 1884 a fellow student, Margaret Middelberg of Amsterdam, who died in 1925. Five years later he married Mrs. Teterode, by whom he is survived.

F. E. WEISS.

Prof. J. Versluys

THE death is announced, at the age of sixty-six years, of the eminent Dutch zoologist, Prof. Jan Versluys, professor in the University of Vienna.

Versluys was a fine, tall man, with a fluent command of English, German and French, and was well known to, and highly respected by, many British zoologists who met him either abroad or in Great Britain on the occasions when he attended the meetings of the British Association. He was a pupil of his life-long friend the late Prof. Max Weber of Amsterdam.

As a young man, Versluys accompanied Max Weber as a naturalist on the memorable voyage of S.S. *Siboga* on its marine exploration of the seas of the Malay Archipelago during 1899-1900, and on

his return to Holland wrote the monographs on the two families of the Gorgonacea—the Chrysogorgiidae and Primnoidae—collected by the Expedition. The care he took in the description of the species, his skilful illustrations and his references to type specimens, which he examined whenever available, have rendered these monographs of extraordinary value and interest. They are still the standard works on the subject. After the completion of his work on these coelenterates, he turned his attention to the study of the skull of reptiles and published his first paper on the morphology of the columella bone before he left Amsterdam. In 1904 he migrated to Germany and became a *Privat Dozent* and later an assistant professor in the University of Gießen, and during the following ten years he produced several papers on the skulls of recent and fossil reptiles bearing on what he called “Das Streptostylie Problem”, or the mobility (kinetism) of the bones of the jaws on those of the brain case.

At the outbreak of the Great War, Veraluys remained in Germany, but after the occupation of Belgium by the German army he was appointed a professor in the Flemish University in Ghent and remained there until the Armistice. Returning to Holland, he made a home in the beautiful town Hilversum and there he began a study of another subject, which he called “Das Limulus problem”. Working in collaboration with R. Demoll, of Munich, a number of papers were published on the appendages and other structures of recent and extinct Arachnoidea, especially of *Limulus* and the other Merostomata.

The general conclusions reached by these authors were startling in their originality but have not been accepted by most of the zoologists in Great Britain. They suggested that the evolution of *Limulus* was on lines exactly the reverse of those suggested by Sir Ray Lankester in his well-known essays on this subject. *Limulus* was derived, according to their view, not from an aquatic but from an air-breathing, tracheate ancestry; and, moreover, that even the Crustacea are descended from a remote terrestrial group of animals of which *Peripatus* is the only living representative.

After a few years in Holland, Veraluys accepted the position of professor in the University of Vienna and remained there until his death. I have not been able to find any record of his original work in this last period of his life, except an abstract of a paper he read at the British Association meeting in 1934, on the distribution of the Primnoidae with reference to the Wegener hypothesis.

He leaves a widow and three children.

SYDNEY J. HICKSON.

Eng.-Commander J. J. Walker

THE death on January 12 of Eng.-Commander James John Walker will be deeply regretted by very many British naturalists, especially by students of his favourite insects—Coleoptera and Lepidoptera.

Elected in 1878, Walker had been for some years the senior fellow of the Royal Entomological Society

of London, and was president in 1919 and 1920, his two addresses being on “The Fringes of Butterfly Life” and “Some Aspects of Insect Life in New Zealand” (*Proc.*, 1920 and 1921). Two of his papers in the *Transactions* of 1890 and 1895 dealt with Lepidoptera from the Straits of Gibraltar and the butterflies of Hong Kong, respectively, while the *Proceedings* (1907–31) includes many of his interesting notes on British and a few on foreign insects. The vast majority of his observations made on voyages and at home appeared, however, in the *Entomologist's Monthly Magazine*, of which he became editor in 1904, on the death of Robert McLachlan. The first of his notes and papers in this excellent journal—more than three hundred in number—appeared in 1872, and the last, dated December 20, 1938, less than a month before his death, was published in January. It records the more interesting of fully three hundred species of Coleoptera which he had observed in about thirty acres of meadow and cultivated land between his house and the River Owerwell.

Among Walker's papers were many on interesting subjects which he always kept in mind and added fresh records as they came to light. Such were his notes in 1908, 1911, 1912, 1928 and 1931, on immigrant insects which invaded Great Britain; in 1922, on butterflies which have reached Iceland and on the Lepidoptera of North Atlantic islands; in 1931, on insects at sea; in 1914, 1915 and 1928, on the Monarch butterfly, *Danous plexippus*, and its migrations. Among the many British localities from which he published records the most frequently named are, Isle of Sheppey, Sheerness, Chatham, Kent, Portland, New Forest and especially Oxford, which became his home in May 1904. The honorary M.A. was conferred on him by the University in the following year.

Walker was a constant visitor to the Hope Department of Entomology in the University Museum, Oxford, where he gave immensely valuable help in describing, arranging and recording the historic collections. He joined the Ashmolean Natural History Society in 1904, became president in 1913–14 and from 1911 onwards was editor of the *Proceedings*, in which he published (1907–30) a valuable list of Oxford Coleoptera with supplements; also twenty-three interim reports (1911–38), the last four including Lepidoptera in addition to Coleoptera.

The above is a very condensed account of some of the chief publications of one who, in spite of his great age—eighty-seven years—retained to the very end his wonderful memory, keen interest and the never-failing desire and ability to help his brother-naturalists.

E. B. POULTON.

Prof. Albert Sauveur

PROF. ALBERT SAUVEUR, emeritus professor of metallurgy in Harvard University, whose death occurred recently in Cambridge, Mass., was a Belgian by birth, but was long known as the leading teacher of metallurgy in the United States.

Born at Louvain in 1863, he studied in the School of Mines of Liège, and later crossed the Atlantic to enter the Massachusetts Institute of Technology.

where he graduated in 1889. His first post was as chemist to the Pennsylvania Steel Co.; but after a year he was chosen to take charge of the research laboratory of the Illinois Steel Co. in Chicago. From that time onwards he carried out many researches on iron and steel, making great use of microscopical methods, a field in which there were still few workers. His first paper on the microstructure of iron and steel appeared in 1893 and had many successors. In 1905, he was appointed to the chair of metallurgy at Harvard, which he occupied until his official retirement in 1935, with an interval from 1917 until 1919, during which he acted as director of the Metallurgy Division of the Air Service in France, work recognized by his appointment as a Chevalier of the Legion of Honour.

Sauveur's investigations were concerned almost exclusively with the metallurgy of iron and steel, especially with the problems of hardening and of deformation. His contributions, clearly expressed and admirably illustrated, have played an important part in the development of the subject. In 1898 he founded a journal, the *Metallographist*, which became the medium for the publication of much original work from many countries. Although it lasted only for five years, being then absorbed into another journal, its volumes are often consulted by students. His text-book, "The Metallography and Heat Treatment of Iron and Steel", which first appeared in 1912, has passed through several editions, and is greatly valued. A few years ago he discussed, in the form of a dialogue, the current views on controversial questions in metallurgy.

Sauveur's department at Harvard was small in comparison with the metallurgical departments of many universities and colleges; but the quality of its work was excellent, and many of the ablest American research workers in that field received their training there. He had great charm of manner as well as great gifts of exposition, and was revered by metallurgists as one of their leaders. Even in his retirement he continued to be active, and only last year he initiated a movement with the object of simplifying the description of the microscopic constituents of steel, which he considered to have been obscured by unnecessarily complex hypotheses and cumbersome terminology.

Sauveur received many honours from technical societies, including the Bessemer Medal of the Iron and Steel Institute in 1924. He married, in 1891, Mary Prince Jones, of Massachusetts, and had two daughters.

C. H. D.

Mr. Reynold Bray

MR. REYNOLD BRAY, who lost his life by drowning last September, was an Arctic explorer of considerable achievement and much promise. In 1931, he was with the Oxford University Exploration Club's Expedition to Akpatok in Ungava Bay, Hudson Strait. This expedition, on which Bray was nominally photographer, made a complete survey of this hitherto little-known island. The story was told in "The Tale of Auks" by N. Polunin, 1932. In the follow-

ing year Bray, with T. H. Manning, made a winter tramp through Swedish, Finnish and Russian Lapland from Bodo to Murmanak. Bray recounted this fascinating journey, which included trouble on the Soviet frontier, in "Five Watersheds" (1935). In the following year he was again with Manning, in Southampton Island and Melville peninsula mapping much of the eastern shores of those lands as well as the unknown coast of Baffin Island on the east of Foxe basin.

In 1938, Bray planned with P. Baird to continue his exploration of the western coast and the interior of Baffin Island. Ice, however, interfered with the ship's progress and eventually the two men were landed on the south-east of Melville peninsula, whence they set off in their boat last August in an attempt to reach Igloodik Island, 300 miles to the north at the eastern entrance to Fury and Hecla Strait. Some forty miles south of the island, on September 14 last year, Bray was blown out to sea in a canvas boat and lost.

Mr. R. Kanthack

THE late Mr. Ralph Kanthack, who died in his seventy-seventh year at Golders Green, London, on November 12, was chiefly known for his great ability in scientific translations in English and German. He was educated in Hamburg and Lüneburg, Germany, taking an honours degree in engineering. After some period as a marine engineer, he found himself more attracted to scientific and optical studies, and became associated with Messrs. Carl Zeiss, when he had the advantage of intimate association with Abbe, Czapski and others. This led to his establishment as a London agent for Messrs. Carl Zeiss and Messrs. E. Leitz; but in addition to business activities he was known as an authority on various aspects of microscopy.

In later years, Kanthack began the literary work which brought him well-deserved recognition. He translated and revised a German edition of Prof. Heath's work on geometrical optics ("Lehrbuch der Geometrischen Optik". Berlin: J. Springer, 1894), and during the Great War he translated von Rohr's "The Theory of Optical Instruments" at the request of the British Government. Later, he was associated with Messrs. Adam Hilger, Ltd., for whom he prepared a book in two volumes entitled "Tables of Refractive Indices".

Mr. Kanthack was the eldest son of the late Emilio Kanthack, at one time British Consul of Para, Brazil, and brother of the late Prof. Alfredo A. Kanthack, an authority on pathology. He was much respected in optical circles for his outstanding character.

We regret to announce the following deaths:

Prof. A. P. Coleman, F.R.S., emeritus professor of geology in the University of Toronto, an authority on Canadian metalliferous deposits, on February 27, aged eighty-six years.

Prof. Henry Louis, emeritus professor of mining and William Cochrane lecturer in metallurgy in Armstrong College, Newcastle-upon-Tyne, on February 22, aged eighty-three years.

News and Views

Prof. F. J. Cole, F.R.S.

PROF. F. J. COLE will be retiring from the chair of zoology in the University of Reading in September next, after a tenure of thirty-two years. Prof. Cole built up the Zoology Department from very small beginnings; to-day the University can regard with pride the results of his work and inspiration. The Museum of Comparative Anatomy, though small, is without a rival among those of the younger universities, and the preparations, dissections and models have been executed in the Department. Even the printing of the labels is done there. This Museum has justifiably achieved widespread fame; recently a former keeper of zoology in the British Museum (Natural History) referred to it as the "gem" among British museums of comparative anatomy. Although assisted by a very small, but efficient staff, the organization of the teaching side of the Department has always been of the first class. Until comparatively recently, few students entered a university with even the most elementary knowledge of zoology; but those who were fortunate enough to study the subject at Reading soon became infected with the enthusiasm of Prof. Cole and his staff, and by far the majority became sincere students of the subject, not merely candidates reading for an examination.

PROF. COLE's researches on the nervous system and lateral line system of fishes and on the general morphology of the myxinoïd fishes are well known. In recent years his strong literary bent, scholarly mind and acquisitive love of books have combined to interest him in the history of zoology. He has lectured and written on the biologists of the past, extending to them the same sympathetic understanding of their difficulties and mistakes that he offers to young people struggling along the paths of original investigation under his care, yet always, after the manner of Gibbon, relieving the tedium of instruction with an apt analogy or an appropriate anecdote. Last year, with the collaboration of Mr. Robert Gibbings, he produced a facsimile reprint of a very rare book—"*Observationes Anatomicae Selectiores. Amstelodamensium. 1667-73*" (see *NATURE*, 142, 235; 1938). His researches into the writings of Leeuwenhoek and Swammerdam have taken him to the old towns and museums of Holland. As a result several papers have appeared in the *Annals of Science* and other journals devoted to the history of science. As Prof. Cole will now be able to devote all his time to his unique collections of early medical books we look forward to more of his delightful studies of the biologists of the past.

Prof. Otto Hahn

ON March 8, Prof. Otto Hahn, director of the Kaiser Wilhelm-Institut for Chemistry, at Dahlem near Berlin, will reach his sixtieth birthday. To mark this event, a special number of the *Zeitschrift für*

physikalische Chemie will appear, in which all the articles will be contributed by members of his laboratory. A celebration of a more intimate nature is also contemplated in the Institute itself. Prof. Hahn's friends in other countries, among whom are many readers of *NATURE*, will wish to join with his colleagues in offering their warmest congratulations. To workers and students in the field of radioactivity the names of Otto Hahn and Lise Meitner are almost indissolubly linked together. Readers of *NATURE* will remember that Fräulein Lise Meitner celebrated her sixtieth birthday last November, and it is most fitting that where one has led the other should not be far behind. Prof. Hahn's first work in radioactivity was an investigation of the activity of thorianite, carried out under Ramsay at University College, London. This work led to the discovery of a new radioactive substance, radiothorium. Attracted by the rapidly growing fame of Rutherford, he then went to Montreal for a year (1905-6). There he discovered a new body, radioactinium, in the actinium series and showed that there were marked similarities between the products of thorium and actinium. On his return to Berlin, there followed the discovery of mesothorium and some striking experiments on the use of the recoil phenomenon as a method of separating radioactive products. It was at this time that his association with Fräulein Meitner began. Together they examined the radiations from many radioelements and later, with von Baeyer, they discovered the presence of homogeneous groups in the β -radiation of some products, the first indication of the now well-known β -ray spectra.

Hahn and Meitner also made investigations on the origin of the actinium series and, in 1918, they discovered, simultaneously with Soddy and Cranston in Great Britain, the immediate parent of actinium, protactinium. Later Hahn prepared this new element in a pure state in quantity sufficient for an atomic weight determination. In pursuing his investigations of the disintegration products of uranium, Hahn found a very curious branching of uranium X_1 , which gave rise to two bodies—uranium X_2 , already known, and uranium Z , a new product of the same mass and charge as uranium X_1 , but with different radioactive properties. This was in fact the first example of a pair of nuclear isomers, many of which have recently been found as a result of artificial transformations. In recent years, much of Prof. Hahn's work has been devoted to a study of the artificial transformations resulting from the bombardment of uranium and thorium by neutrons. Only a few weeks ago he was able to show, on chemical evidence, that one of the products of the disintegration of uranium was not, as previously supposed, an isotope of radium but an isotope of barium, pointing to a really dramatic disintegration of the uranium nucleus. This startling conclusion has been confirmed by very striking

experiments in New York, Paris and other places. It will be evident from this very brief account of his work that Prof. Hahn's contributions to radioactivity have been of outstanding importance. He has also taken a prominent part, with his students and colleagues, in developing methods of studying chemical problems by the use of radioactive indicators.

Dr. C. D. Darlington

DR. C. D. DARLINGTON has been appointed to succeed Sir Daniel Hall as director of the John Innes Horticultural Institution, Merton. Dr. Darlington was educated at St. Paul's School, Hammersmith, where he was a Foundation Scholar, and the South-Eastern Agricultural College, Wye. He went to the John Innes Horticultural Institution in 1923, in Dr. Bateson's time. Here his interest was attracted to chromosome studies by the late W. O. F. Newton. As the importance of this kind of work in relation to breeding became recognized, it was considerably extended at the John Innes Institution, and in 1937 Dr. Darlington was appointed head of the Cytology Department. In 1929, he travelled to Persia and Transcaucasia to investigate the origin of cultivated forms of *Prunus* and *Tulipa*. During 1932-33, he worked in the United States for eight months as a Rockefeller Foundation Scholar, visiting Japan and India on his way home. In the winter of 1937-38, he was a delegate to the Indian Science Congress jubilee meeting. He is at the present time acting as recorder to the Cytology Section of the International Genetical Congress. Dr. Darlington, who is well known for his work in the field of genetics and cytology, has published "Chromosomes and Plant Breeding" (1932), "Recent Advances in Cytology" (1932; second edition 1937), "The Evolution of Genetic Systems" (1939), together with numerous scientific communications. He is a collaborating editor of the new journal *Chromosoma* (see p. 372 of this issue). The appointment takes effect from October 1, 1939.

Mr. James Henderson

THE Iron and Steel Institute has awarded the Bessemer Gold Medal to Mr. James Henderson. The Bessemer Medal was founded by Sir Henry Bessemer, and is awarded annually for distinguished merit in promoting the technical and metallurgical development of the iron and steel industry; it is the highest honour which the Institute can give. Mr. Henderson was associated for forty-five years with the technical development of the Frodingham Iron and Steel Co., Ltd., in North Lincolnshire and held all positions from chief metallurgist to managing director. During that period, the works became one of the most important in the country, and were associated with such important developments as the introduction of the Talbot direct metal process, the use of blast-furnace gas in blowing and power engines, and the installation of modern plate mills. Mr. Henderson is now deputy chairman of the renamed Appleby-Frodingham Steel Co., Ltd., and a director of the United Steel Companies, Ltd.; he is past-president of the British Iron and Steel Federation and of the Lincolnshire Iron and Steel

Institute. He is one of the only two Englishmen whose services to the industry have been recognized by nomination to honorary membership of the Verein deutscher Eisenhüttenleute.

Ludwig Mond, F.R.S. (1839-1909)

LUDWIG MOND, patron of the arts and sciences, was born on March 7, 1839, and the commemoration of his centenary is a convenient opportunity to recall something of what we owe to him. Originally German and later a naturalized British subject, he perfected and established in Great Britain the ammonia-soda process which brought into being the firm of Messrs. Brunner, Mond and Company, the nucleus of Messrs. Imperial Chemical Industries, Limited. He also devised satisfactory processes of nitrogen recovery and for the manufacture of producer gas, which latter process is the property of the Power Gas Corporation. No less well known is Ludwig Mond's process for the production of pure nickel, in which a newly discovered and unique compound immediately found important technical application. Throughout his life, he was pre-eminent as a chemist and investigator. His amassing great wealth was the result and not the object of his work.

SOME of Ludwig Mond's public benefactions for the encouragement of scientific investigation may be recalled. During his life he gave £100,000 for the founding and endowment of the Davy Faraday Laboratory of the Royal Institution, and £16,000 for the continuance and improvement of the catalogue of scientific papers of the Royal Society. He bequeathed £50,000 to the Royal Society "for the endowment of research in Natural Science more particularly but not exclusively in Chemistry and Physics". He also bequeathed a similar sum to the University of Heidelberg and £25,000 to Cassel, his native town in Germany. He gave to the nation, together with an endowment for its maintenance, the Mond Collection, chiefly of early Italian paintings, now well known as an important part of the National Gallery. This, and his bequest of £20,000 to the Munich Akademie der bildenden Künste, are memorials to Ludwig Mond's own appreciation of art and to the care he took that others should benefit by it. Truly, this was a great man.

Frederick Howard Marsh (1839-1915)

HOWARD MARSH, an eminent London surgeon and master of Downing College, Cambridge, was born on March 7, 1839, at Homersfield, near Bungay, Suffolk, the son of a gentleman farmer. He received his medical education at St. Bartholomew's Hospital, where he was a contemporary of Alfred Willett (see NATURE, 139, 61; 1937) and qualified L.S.A. and M.R.C.S. in 1861. Five years later he became F.R.C.S. and was appointed surgeon to the Queen Square House of Relief for Children with Chronic Disease of the Joints. In 1868, he was elected assistant surgeon to the Great Ormond Street Hospital for Sick Children, where he afterwards became full surgeon and consulting surgeon. Between 1865 and

1870 he acted twice as private assistant to Sir James Paget, several of whose works he afterwards edited. From 1873 until 1891, when he became full surgeon, he served as assistant surgeon to St. Bartholomew's Hospital, where he lectured on anatomy, practical surgery and orthopaedics. In 1903 he was appointed professor of surgery at Cambridge in succession to Sir George Murray Humphry, who had died in 1896, and in 1907 succeeded Dr. Alexander Hill as master of Downing College. He was the author of "Diseases of the Joints" (1886), which went through three editions and was translated into German, "Clinical Lectures and Essays" (1902) and numerous contributions to *St. Bartholomew's Hospital Reports*. Besides the distinctions already mentioned, Marsh was an honorary fellow of the Royal Academy of Medicine in Ireland, president of the Clinical Society of London and a corresponding member of the Orthopaedic Society of New York. He died on June 24, 1915. A sympathetic obituary notice by Sir D'Arcy Power, accompanied by his portrait, appeared in *St. Bartholomew's Hospital Reports* (51, 1; 1915).

The Bastardy (Blood Tests) Bill

It is to be hoped that the Bastardy (Blood Tests) Bill, which was given its second reading after a debate in the House of Lords on February 8 (NATURE, Feb. 18, 1934), will duly pass into law. The use of blood group tests has already become a common practice in several other countries, notably Sweden, Germany and the United States. The Bill provides that the Lord Chancellor may make rules under the Act, governing the taking, identifying and posting of blood samples, the form of certificate to be given, the qualifications of the 'approved persons' who make the tests, and the scale of fees payable. It may be pointed out that the *M* and *N* tests require much more skill in determination than the *A* and *B*. It would therefore seem desirable for a local practitioner to take the samples as arranged and send them to one of a very limited number of experts who would make the actual tests. The Galton Laboratory is one of the very few places where the *M* and *N* as well as the *A* and *B* tests are constantly being made as a routine operation. In Denmark, a Government laboratory has been established for the purpose, where the tests are made for a small charge. Probably a similar arrangement would be best for Great Britain.

Television in Cinemas

THE practical application of television moved a step forward on February 23, when a view of the whole progress of the British light-weight boxing championship was transmitted from the Harringay arena. On this occasion, for the first time, the television programme was relayed to three cinema theatres in the West End of London, where the public had paid for admission. A report in *The Times* states that two of these theatres used Baird apparatus, while the third used the Scopophony system. These cinemas became in effect overflow meeting places, where those unable to watch the fight in the arena could still follow its progress in black and white

pictures; and the view so provided on a fifteen foot screen was the equivalent of a ring-side seat. At the transmitting end, two cameras were used, one giving a general view of the ring with the spectators scarcely visible in the surrounding darkness, while the other gave a close-up view of the two boxers. The latter was used most of the time and enabled viewers to watch the detailed progress of the contest. With the exception of one or two occasions, when there appeared to be a loss of synchronism in the transmitted pictures, the apparatus worked quite satisfactorily, and the accompanying running commentary was up to the usual high standard for sound broadcasting. The successful transmission of this fight demonstrated that such an event is very suited to television, and that the inevitable technical difficulties of relaying the programme to cinemas have been largely overcome. As a result, according to a further announcement in *The Times*, Baird television apparatus is to be installed in some 350 cinemas controlled by the Gaumont-British Picture Corporation.

University of Birmingham: Annual Report

IN the report of the Council which was presented to the Court of Governors at its annual meeting on February 23, reference is made to two recent benefactions, namely, one of £10,000 by Sir Charles Hyde and the other of £2,000 by the Pro-Chancellor and Mrs. Barrow. These were given as peace thank-offerings. Sir Charles Hyde's gift, to be applied to a purpose chosen by the Prime Minister, is to be known as the Neville Chamberlain Physical Fitness Fund, and the income is to be used towards the maintenance of the University's scheme for physical education. The contribution of Mr. and Mrs. Barrow is to be added to the Medical School building fund. Mrs. Ellen M. Parrott has given £500 in memory of her late husband, to be known as the T. H. Parrott Geological Research Fund, for 'advancement of research in Geology'. Dr. and Mrs. Edward Cadbury, who recently provided funds for the building of the St. Francis Hall, have given a further sum of £3,000, the income of which is to be used for the maintenance of the Hall. As part of the scheme for physical education, a gymnasium (with ancillary rooms and three squash courts and one fives court) is to be built at a cost of £15,000, of which £10,000 has been promised by the University Grants Committee and £5,000 by a private benefactor. Funds for the establishment of a department for research into mental diseases in the new building of the Medical School have been guaranteed for a number of years. The laboratories are now occupied, and Dr. Stanley Barnes has been appointed honorary director of mental diseases research, with Dr. F. A. Pickworth as senior research officer. Several investigations into cancer, financed by the Local Committee of the British Empire Cancer Campaign, are being carried out in the new Medical School. The Poynting Memorial Lecture is to be given on March 7 in the Physics Department by Dr. H. B. G. Casimir, of Leyden, on "The Approach to the Absolute Zero of Temperature, and the Properties of Matter at the

Lowest Attainable Temperatures". The Huxley Lecture is to be given on March 16 at the University, Edmund Street, by Sir Albert Seward on "Aspects of Evolution in the Plant World".

Vocational Rehabilitation of the Physically Disabled

A STUDY of the vocational rehabilitation of the physically disabled has been prepared for the Advisory Committee on Education by Lloyd E. Blanch (U.S. Government Printing Office, Staff Study No. 9). The study reviews the development, status and problems of the rehabilitation service inaugurated in July 1920 by the Federal Government, under which up to June 30, 1937, 98,690 persons had been rehabilitated. In the year ended June 30, 1937, vocational rehabilitation was completed for 8,691 men and 2,400 women, about 60 per cent of whom received some training. Maintenance was provided or secured for 948 while they were undergoing rehabilitation. Of those rehabilitated, 64 per cent were less than thirty-one years of age and only 8 per cent were more than fifty. Most of those rehabilitated (61 per cent) were without dependants, but 26 per cent had two or more dependants. Orthopaedic disabilities handicapped 75 per cent of those rehabilitated. The study suggests that 150,000 persons each year acquire permanent disabilities sufficiently serious to prevent them from returning to work without assistance. About 50,000 of these can be employed normally after rehabilitation; 75,000 can be employed only in sheltered workshop conditions, while the remaining 25,000 can only be employed, if at all, in their homes. Accordingly the present programme only rehabilitates about 20 per cent of the physically disabled who need such assistance. The study concludes that a permanent Federal programme is required and insists on the importance of Federal administration and of the co-ordination of Federal services which affect vocational rehabilitation. Reference is also made to special services for the blind and to the need for an extended programme, including the provision of living expenses during rehabilitation.

The New Deal in the United States

In *Fact* of October 1938, under the title "Roosevelt and his New Deal", Stephen K. Bailey gives a concise account of the achievements of the New Deal up to the end of September, which indicates not merely the problems which faced Roosevelt but also the background of social and economic conflict against which they have to be assessed. In successive chapters, the attempts made to meet the needs of the farmer, under the Agricultural Adjustment Administration and the Farm Credit Administration, etc., the industrialist, under the National Industrial Recovery Act and the Public Works Administration, as well as the needs of labour and the unemployment situation by the Federal Relief Administration, are surveyed. The complexity of the situation is clearly indicated as well as the way in which the conflict between big business interests and labour has been intensified, the difficulties which the Federation has to overcome in the direction of social reform, the establishment of a really sound banking system, and the problem

of the Supreme Court. Mr. Bailey hazards no guess as to the outcome of the present situation: the successes and failures of the New Deal are impartially indicated as well as some of the reasons for the vagaries of American foreign policy; but his account, whether or not it is used as an introduction to further study, should at least contribute to the sympathetic understanding of the American situation, although the rather sombre picture he gives of the relation between employers and employees and of the attitude of the former to social reform does not encourage optimism.

Selection of Sizes of Timber Beams

THE determination of the suitable breadth and depth of a timber beam to carry a given load involves consideration of strength, of stiffness, and of the capacity of the material to withstand the horizontal shear forces induced in it by the transverse loading. The calculations which these considerations necessitate can, however, be entirely eliminated by making use of a set of three charts recently published under the title "Charts for the Design of Timber Beams". These charts have been prepared by V. D. Limaye, officer-in-charge of the Timber Testing Station, Forest Research Institute, Dehra Dun, United Provinces. The first of them is designed to ensure that a beam of adequate strength is chosen. In it two nomographs are provided which, from the given load per square foot, span, and spacing, ascertain the total load carried by the beam. Then, by the drawing of four horizontal and vertical lines terminated by suitably placed diagonal lines which are embodied in the chart, the breadth and depth of a sufficiently strong beam are obtained. In most cases in which timber beams are used, it is necessary to restrict the deflection under load to certain specified limits, and stiffness has therefore to be arranged. This is done by means of the second chart, which enables the correct amount of adjustment to be made in the sizes already determined so that the required degree of stiffness is assured, and the process involves only the drawing of another set of horizontal and vertical lines. In the third chart a third series of horizontal and vertical lines leading to a final nomograph either confirms the horizontal shear strength as adequate or shows the correction required so that, in the end, the section evolved is suitable for its purpose from all points of view.

Magneto or Coil Ignition for Motor-Cars

F. R. HAIGH has recently compared the relative advantages of magneto and coil ignition used for generating the explosions which occur in motor-car engines (*Students' Quart. J. Inst. Elec. Eng.*, Dec.). Coil ignition was prominent on the early types of petrol engines, but magnetos appeared on the market and for a number of years prior to 1914 a Bosch magneto was regarded as the acme of perfection. About ten years ago coil ignition systems came to the front. The magneto is of great importance in aero work and is popular on racing-cars, but in motor-vehicles it has been almost entirely replaced by coil ignition. Modern coil ignition systems are

very trustworthy. The causes of the failure of the ignition system are almost always due to battery and wiring faults; they are very rarely due to the ignition apparatus itself. The contact breaker, coil and ignition switch are generally mounted at different points and thus their action is dependent on the soundness of the wiring between them. Loss of magnetism which used to cause trouble with magnetos is absent in coil systems. Ease in starting up an engine is a prominent feature in coil ignition; at whatever speed the engine is turning, a good spark is always obtained at the plug points. The contact breaker is usually the first component to be examined following an ignition failure, and hence its accessibility and ease of adjustment are of great importance. In this respect, coil ignition has nearly always the advantage. A clear view of magneto contact breakers can rarely be attained without the aid of a mirror. Coil ignition is also greatly superior to the magneto so far as the rapid replacement of faulty parts is concerned.

Scandinavian Museums

AN article by J. A. Sidney Stendall on museums in Scandinavia (*Museums J.*, 38, 397, Nov. 1938) should prove of value to museum curators in Great Britain. The author selects for special description details of exhibition technique. His diagrams of methods of showing specimens, of artificial lighting, and of construction of exhibition cases for straightforward display or for the building up of pictorial dioramas, show how carefully and successfully these aspects have been considered in the museums of Sweden. There are suggestions here the adoption of which would add interest to many museums in Great Britain.

Chromosoma

THE development of the chromosome theory of heredity during the last twenty years has led to the publication of some thousands of papers devoted to a study which is at once genetics and cytology. These papers have been published partly in the special genetical journals—*Genetics*, *Bour's Zeitschrift*, *Genetica*, *Hereditas* and the English and Japanese *Journals of Genetics*—and partly in the special cytological journals—*La Cellule*, *Cytologia* and *Messrs. Springer's Zeitschrift für Zellforschung und mikroskopische Anatomie*. Many also have been published by the older zoological, botanical and general scientific journals. *Messrs. Springer* have now divided their journal into two parts, which will appear separately this month, marking not inappropriately the centenary of the cell theory. Part A, *Allgemeine Zellforschung und mikroskopische Anatomie* will continue to deal with the physiological and histological side of cell-study with which the old journal was largely concerned. Part B, under the short title of *Chromosoma*, will be in effect a new journal. It will deal with the chromosomes in their twin aspects of cell mechanisms and organs of heredity. Dr. Hans Bauer, of the Kaiser Wilhelm-Institut für Biologie in Berlin-Dahlem, is the general editor. He has secured the collaboration of Dr. Lothar Geitler of Vienna,

Dr. T. Caspersson of Stockholm, Dr. A. Müntzing of Lund, Dr. W. v. Möllendorf and Dr. J. Seiler of Zurich, Dr. O. L. Mohr of Oslo, Dr. C. D. Darlington of London, Dr. F. Schrader of New York, and Dr. Th. Dobzhansky of Pasadena. The balance of zoology and botany, chemistry and genetics in this group should ensure a competent discrimination as well as a new point of view in furthering this youngest of the sciences.

Sixth Pacific Science Congress

THE sixth Pacific Science Congress will be held in Berkeley, Stanford and San Francisco, California, during July 24–August 12 under the auspices of the National Research Council of Canada, on the invitation of the U.S. National Research Council. The programme is so constituted as to emphasize the discussion of comprehensive scientific topics of general interest to the peoples living within the Pacific basin, and the theme of the Congress will therefore be “the present stage of knowledge of Pacific scientific problems and methods by which that knowledge may be most profitably enlarged”. For this reason, the programme is arranged as a series of symposia rather than a collection of independent papers. Forty-two countries have been invited to take part. Further information can be obtained from Dr. R. E. Clausen, Room 205, Hilgard Hall, University of California, Berkeley, California.

Study Meeting on Magnetism

A STUDY meeting on magnetism, to be held in Strasbourg during May 21–25, is being organized by the Institute of Intellectual Co-operation in collaboration with the Service Central de la recherche scientifique de France. The following subjects will be discussed: (1) paramagnetism, very low temperatures, relaxation and nuclear magnetism; (2) optics and paramagnetism, low temperatures and moderately low temperatures; (3) ordinary paramagnetism; (4) ferromagnetism, (a) atomic and molecular moments, (b) ferromagnetism and the crystalline network, (b') interaction and its relationship to thermodynamics, (c) Curie points, (d) gyro-magnetic phenomena. A number of papers have already been arranged, and it is expected that about thirty eminent authorities on the subject will attend the meeting. The papers and a report of the discussions will be published in the fifth volume of the “Scientific Collections” of the Institute. Further information can be obtained from the International Institute of Intellectual Co-operation, 2 Rue de Montpensier, Paris, 1^{er}.

Physics in the Textile Industries

THE annual general meeting of the Manchester and District Branch of the Institute of Physics is to be held in the Physics Department of the University of Manchester at 7.30 p.m. on Friday, March 17. Immediately after the conclusion of the business of the meeting, Dr. F. C. Toy, chairman of the Branch, will speak on “The Physicist in the Textile Industries”, and will attempt to give some idea of the vast scope in textile research for the employment of theoretical

and applied physics, and for the application of physical methods. In view of the Institute of Physics forthcoming Conference on Textile Physics it may be expected that Dr. Toy's lecture will be of special interest to members of the Institute, and to others connected with the textile industries.

Conference on Industrial Physics

THE third Conference on Industrial Physics is being arranged by the Institute of Physics to take place in Leeds during March 23-25 under the presidency of Prof. R. Whiddington. The subject of the Conference is to be "Physics in the Textile Industries". An exhibition of instruments, apparatus and books cognate to this subject is being arranged and will be held in the Physics Laboratories of the University of Leeds. A section of the Exhibition, intended to be of special interest to non-technical persons, will be devoted to popular applications of physics in the textile industries. Addresses will be given by the president of the Institute of Physics, Dr. C. C. Paterson, on "Colour and Colour Rendering" and by Dr. C. G. Darwin, director of the National Physical Laboratory, on "Heat Effects in Fibres and other Systems". In addition, the following lectures, to be followed by discussions, have been arranged: "The Physics of Humidity" by Prof. R. Whiddington; "Industrial Humidity Control and Measurement" by Dr. Ezer Griffiths; "The Contribution of Physics to the Development of Industrial Process Control" by Dr. M. C. Marsh; and "Automatic Regulators for the Textile Industries" by Mr. D. Harrison. Visits to local works and research laboratories will be included in the programme, and a Conference dinner is being arranged. There will be no Conference fee, and membership is open to all interested. Further particulars can be obtained from the Secretary, Institute of Physics, 1 Lowther Gardens, Exhibition Road, London, S.W.7.

Announcements

THE following awards have recently been made by the Royal Academy of Belgium: Charles Lemaire prize to E. Franchimont; François Deruyts prizes to P. Burniat and F. Rozet; Léo Errera prize to A. Daleq; Joseph Schepkens prize to R. Steysert; Adolphe Wetremis prize (natural sciences) to C. Stevens; Albert Brachet prize to L. Sven Horstadius. The Paul Fourmarier prize to L. Cayeux. Prof. H. N. Russell, of Princeton, and Prof. A. Pietet, of Geneva, have been elected associates of the section of mathematical and physical sciences of the Academy.

COSTANTINO GORINI has been elected *correspondant* for the Section of Rural Economy of the Paris Academy of Sciences in succession to the late L. Ravas.

THE following awards have been made by the Council of the Royal Aeronautical Society: *Silver Medal*: Major R. H. Mayo, for his work leading to an advancement in aeronautical design; *Taylor Gold Medal*: Squadron Leader H. P. Fraser, for his paper on "High Wing Loading and Some of Its

Problems from the Pilot's Point of View"; *Wakefield Gold Medal*: Mr. Leslie L. Irvin, for his work on parachute design, which has led towards safety in flying; *Bush Memorial Prize*: Squadron Leader G. M. Buxton, for his paper on "The Development of Sailplanes", and to Mr. H. F. Vessey, for his paper on "Effect of Wing Loading on the Design of Modern Aircraft with Particular Regard to Take-off Problems"; *Filcher Memorial Prize*: Mr. H. E. H. Roehfort, for his paper on "The Theory and Practice of Stressed Skin Construction for Aeroplanes"; *Usborne Memorial Prize*: Mr. P. H. Rayner, for his paper on "Notes on Aero Engine Research".

THE following appointments and promotions in the Colonial Service have recently been made: R. K. Tremlett, agricultural officer, Uganda; J. N. See, veterinary officer, Leeward Islands; W. M. Rogers, tobacco officer, Agricultural Department, Ceylon; O. J. Voelcker, senior botanist, Agricultural Department, Nigeria; N. R. McHardy (senior inspector of plant diseases), land settlement officer, Jamaica.

THE Leipzig Fair will be held on March 5-13. The Samples Fair will be open during March 5-10; but the Great Engineering and Building Fair will be open for the whole time. Further information can be obtained from the London office of the Leipzig Fair, 426-9 First Avenue House, 45 High Holborn, London, W.C.1.

THE Federation of Medical Societies of North Africa will hold its annual congress on April 3-5 at Oran under the presidency of Dr. Jasseron. The subject for discussion will be brucella infections. Further information can be obtained from the general secretary, Dr. René Solal, 16 Boulevard Maréchal Joffre, Oran, Algeria.

THE Royal Statistical Society is offering the Frances Wood Memorial Prize, value £30, for competition in 1939. The Prize is offered for the best investigation, on statistical lines, of any problem affecting the economic or social conditions of the people. Further information can be obtained from the Honorary Secretaries of the Royal Statistical Society, 4 Portugal Street, W.C.2.

WE are asked to state that all reprints of papers of the late Prof. George Barger have been placed in the Department of Chemistry, The University, Glasgow, and copies can be obtained from there on application to the Secretary of that Department.

THE *Proceedings of the Linnean Society*, Part 4, published on December 30, contain, together with the address of the president, Dr. J. Ramsbottom, abstracts of the papers delivered by invitation at the two symposia held by the Society as part of the 150th anniversary celebrations, upon the subjects of "The Concept of Species from the Time of Linnaeus to the Present Day" and "Geographical Isolation as a Factor in Species Formation" (*NATURE*, 141, 998; 1938).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 381.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Forbidden Lines of Fe VII in the Spectrum of Nova RR Pictoris (1925)

THE bright line spectrum of Nova RR Pictoris (1925) is characterized in the later stages by a group of lines in the visible region, of which the most prominent, λ 5723 and λ 6087, form with H α and λ 4686 of He II the dominating lines of the spectrum¹. These lines have not been found in any other spectrum and no adequate explanation of them has been given so far.

Some coincidences between lines in Nova Pictoris and forbidden transitions in Fe VII² suggested a search for analogous lines of Fe VII. Extrapolating the position of the multiplet $3d^3\ ^3F - 3d^3\ ^3P$ in Fe VII, one finds a striking coincidence with a group of lines in Nova Pictoris. The significance hereof is strengthened by the exact reappearance of the separation $^3F_4 - ^3F_2$ between λ 5723 and λ 6087, indicating the identification $^3F_4 - ^1D_2$ and $^3F_2 - ^1D_2$. However, due to the uncertainty in the preceding iso-electronic spectra, the location of ^1D could not be predicted by extrapolation, and a previous analysis of FeVII³ is inconsistent with the suggested identifications. Thus a new attempt at locating the $3d^3$ terms of FeVII became highly desirable. This has now been accomplished, and the result confirms and extends the suggested explanation of the Nova Pictoris spectrum, as will be shown below.

The vacuum spark spectrum of iron photographed with a previously described spectrograph⁴ at 0.5 A. per mm., reveals several line groups involving $3d^3$ terms. The group $3d^3 - 3d\ 4f$ at λ 150 A. to 159 A., which is well separated from other transitions and shows strong intercombinations, was chosen as the most suitable for the purpose. It was possible to classify all (42) observed lines of the group with a tolerance of about 0.001 A. and establish in good agreement with the theoretical formulae⁵ all terms of each configuration, which are able to appear in the group. The details of the analysis will be published elsewhere. The $3d^3$ levels thus located are collected in the following table.

$3d^3\ ^3F_4$	0	$3d^3\ ^3P_2$	20037
$^3F_3$	1047	$^3P_1$	20428
$^3F_2$	2327	$^3P_0$	21275
$^1D_2$	17475	$^3G_4$	23616

The calculated wave-lengths (± 2 A.) of the forbidden transitions between these terms are as follows:

$$\begin{aligned} ^3F - ^1G & 3457.3, 3587.2, 3759.9; \\ ^3F - ^3P & 4099.0, 4993.9, 4943.3, \\ & 4989.4, 5158.3, 5376.1; \\ ^3F - ^1D & 5720.9, 6085.5, 6599.7. \end{aligned}$$

The corresponding lines in Nova Pictoris in 1933; some of which are blends, are 3760.0, 4701.2, 4894.8, 4944.7, 4986.1, 5155.3, 5275.6, 5723.4, 6087.5.

From the comparison it is evident that the complete array of [Fe VII] transitions falling in the investigated region recurs in Nova Pictoris. At the same time, all the lines of hitherto unknown origin in the visible spectrum of the late stages of Nova Pictoris are explained.

The following remarks may be added. The strong 'out of focus' line λ 3760, which was previously ascribed to O⁺⁺, is no doubt mainly due to [Fe VII], although O⁺⁺ may contribute, especially in the earlier stages of the nova. The nebular pair of [Oa V] is certainly present, one component being λ 5308 and the other coinciding with λ 6087. The blend of [Oa V] and [Fe VII] in λ 6087 would explain the observed variation in the intensity ratio between λ 5723 and λ 6087, which has been considered as indicating that these lines cannot have a common origin⁶.

Origin of the Earth's Magnetic Field

THERE is considerable physical evidence that the earth possesses a metallic core¹. Jeffreys² has estimated the viscosity of the core and finds it as low as 10^{19} c.g.s. units. If this value is correct, an intense thermal convection must be maintained in the core by the heat development of radioactive impurities, even if the amount of the latter is exceedingly small compared to their concentration in the earth's crust.

I have developed a tentative theory of the magnetic field based on the assumption that this field is caused by thermo-electric currents in the core which owe their existence to the conditions created by the turbulent convection. The thermo-electric current density is

$$I = \sigma \text{ grad } \omega - B \text{ grad } T, \quad (1)$$

where σ is the conductivity, ω the potential of the space and surface charges, B the thermo-electric constant of the material and T the temperature. σ , B , T are functions of the co-ordinates. If they are given, ω follows as solution of the differential equation $\text{div } I = 0$ together with proper boundary conditions.

It might appear surprising that the local fluctuations of the currents (1) should sum up to yield a resultant magnetic momentum which is approximately parallel to the earth's axis. The reason for this is found in the action of the *Coriolis force* upon the mechanical motions of the fluid mass. A glance at the hydrodynamic equations will show that for small values of the viscosity the Coriolis force is vastly preponderant as compared to all other dynamical effects. This causes a peculiar east-westerly asymmetry of the temperature variations at a given level. The latter variations are, in the usual way, produced by the vertical component of the convective motions.

For the further considerations, we shall confine ourselves to the second term on the right-hand side of equation (1), which presumably contributes the major part of the magnetic momentum. The discussion of the first term is closely analogous. It is readily seen that the magnetic dipole momentum vanishes, if, for a given depth, B is a constant. This means that in a homogeneous mass no temperature fluctuations would produce a magnetic momentum. In addition to the hypothesis of convective motions, we must therefore admit the existence of *inhomogeneities* in the earth's core. Since any particle of the mass undergoes large pressure changes during vertical displacements, the inhomogeneities are best accounted for by phase transformations induced by the pressure changes which are a frequent occurrence at high pressures². Perhaps there are also considerable chemical inhomogeneities present in the core, and while there would be a regular stratification in a state of rest, the distribution of the phases will become irregular under the constant stirring action of the convection.

No additional assumptions have been found necessary. An attempt has been made to estimate roughly the order of magnitude of the thermo-electric currents. Using some simple results of the theory of metallic conductivity, values of σ and B were estimated for iron under the physical conditions of the core. It was found that with temperature differences so low as 10° the current density is of the order of 10^{-4} amp./cm.². This is enough to explain the observed magnetic field as the result of a small one-sided excess in a current system of irregular distribution.

A full account of this investigation will appear shortly in the *Physical Review*.

The Expanding Universe and the Origin of the Great Nebulae

SIR JAMES JEANS¹, commenting on our recent letter², criticizes the numerical relation between the distances between nebulae and their radii following from our point of view on the formation of nebulae. We should like to emphasize here that, owing to the uncertainty of the observational data, the values used by us can only be taken as representing orders of magnitude.

For the diameter of nebulae we used the value

(2,000 light-years) corresponding to spherical nebulae ($E0$) which seemingly represent the theoretically simplest case. If, however, one uses the most elongated nebulae the *average* diameter will be larger only by a factor 2.5 not seriously affecting the general agreement.

The numerical discrepancy of a factor $8\pi^2/9 \simeq 9$ between the exact formula of gravitational instability as developed by Jeans and the simplified one used by ourselves, is due to the fact that Jeans identifies the square of the critical wave-length λ_c , as given in his book, with the square of the *radius* of condensing matter as given by us. This wave-length should be, however, equal to, or larger than, the *diameter* of the condensing sphere; the discrepancy thus becomes less than a factor of two.

The only important modification proposed by Jeans is that instead of Hubble's value 0.8×10^{-26} gm./cm.³ for mean density of matter, he suggests that a larger value 2.5×10^{-26} gm./cm.³ obtained by Sinclair-Smith and others should be used. It should be indicated, however, that whereas Hubble's value for the average mass of nebulae as used by us was derived from the nebular rotation on the assumption that *the nebulae themselves are in a state of equilibrium*, the proposed new value is based on the somewhat arbitrary assumption that the so-called clusters of nebulae are stable. The question as to the status of such clusters is in fact a rather difficult one, and we hope to discuss it in a later publication. Thus it seems more plausible to use Hubble's value which leads to the velocity of particles of the order 100 km./sec. rather than 20 km./sec.

Assuming particles of mass at least equal to that of the hydrogen atom, a temperature of at least 0.4×10^4 degrees C. is obtained. Of course, a pure gas of free electrons could not be responsible for the formation of nebulae; an equal mixture of free electrons and protons (necessary to secure the neutrality of matter) reduces the temperature only by a factor of two.

A more detailed statement of our point of view and its relation to relativistic cosmology is contained in our longer article soon to be published in the *Physical Review*.

After the word "distances" in the eleventh line from the end, the following phrase should be inserted: "which after correction for reddening becomes an apparent increase in density at great distances".

Crystal Structure of Methane at the Transition Point, 20.4° K.

We have made a detailed X-ray investigation of the crystal structure of methane in the transition region, and find, in accordance with previous results¹, that the lattice of methane above and below the transition point is a face centred cube.

In the neighbourhood of the transition point, new lines appear on the photographs apart from those belonging to the face centred cube. We observed as many as five. Some of these lines are quite strong and comparable in intensity with those of the normal lattice. Mooy (*loc. cit.*) has already found evidence of additional lines which he calls parasitic lines.

We have come to the conclusion that these new lines, including the 'parasitic' ones, are essentially connected with the transition and cannot therefore be treated as if they were merely accidental.

A detailed account of this work is to be published shortly.

Spectrum of Singly Ionized Tellurium (TeII)

AN extensive investigation of the spectrum of tellurium as excited especially in condensed discharges through capillary tubes and in vacuum sparks and photographed in the region from λ 7000 Å. to λ 400 Å. has led me to an elucidation of the analysis of the higher spark spectra of the element¹. A further study of the above data has now revealed the structure of the spectrum of singly ionized tellurium (TeII). The lines $\nu\nu$ 86,096, 82,742, 78,447 are identified as forming the fundamental combination $5p^4S - 6S^4P$ which has enabled the extension of the scheme into the region of longer wave-lengths. It has been possible to set up a related system of doublet and quartet terms through the detection of several intercombination lines. The $5p^3D$ and ^1P intervals are found to be 2,734 cm^{-1} and 4,180 cm^{-1} respectively. The structure is analogous to that of SeII worked out by me previously².

Full details of the analysis are being prepared shortly.

Achromatic Lenses employing Lithium Fluoride and Fused Quartz

THE introduction of lithium fluoride in synthetic crystal form (a technique developed by Dr. D. O. Stockbarger¹ and his colleagues at Massachusetts Institute of Technology) has been the means of filling a much-needed want in optical materials. In Great Britain little use appears to have been made of this material. Its chief characteristic is its high transparency from wave-length 1200 Å. up to 20,000 Å.; furthermore, its homogeneity is excellent (even in large crystals) and in this respect is superior to fluoride or quartz.

I made use of this material some two years ago when a vacuum spectrograph² was constructed employing lithium fluoride for the optical components. No deterioration of the surfaces of the prism or lenses of this instrument has been detected during this period.

More recently, I have completed calculations for the design of a lens system (combining lithium fluoride and fused quartz), which gives complete achromatism for a spectral range between λ 5461 Å. and λ 2749 Å. This fact would appear to be of considerable importance, for it means that a lens system designed for use in the ultra-violet part of the spectrum

can be focused in visual light, and no change in focus will be necessary for the ultra-violet. Moreover, a band of ultra-violet wave-lengths may be employed with such a lens system instead of strictly monochromatic illumination, as has hitherto been necessary in the case of ultra-violet microscope lenses.

Lithium fluoride combined with fused quartz achromatic lenses might also be of value for the collimator and telescope lenses of spectrometers used in the ultra-violet region, spectrographs, and possibly photographic lenses.

The suitability of these two materials for achromatizing purposes is clearly indicated in the calculations. The spherical aberration and the offence against the sine condition can also be kept within the permissible tolerances.

The microscope lens system which has been designed is now under construction and the results will be published in due course.

Meteoric Falls in the U.S.S.R.

Meteorite at Kuskochin, Nakhin, Tschernigow, Ukraine. This meteorite fell on June 11, 1938, at about 11^h U.T. (2^h p.m.). The place of the fall is 0.9 km. east of the village of Kuskochin, Nakhin district, Tschernigow region (lat. 57° 03' N., long. 31° 50' E.), 25 km. north-west of the town Nakhin. The sky was quite cloudless; but no conspicuous optical phenomena were witnessed. Acoustic phenomena, resembling the roar of distant thunder or gunfire, were heard over an area of 12 km. radius. Their duration was on the average 8 sec. Three shepherds, G. Pivovarov, I. Miroshnikov and I. Mosko, heard, moreover, a noise and whistle and had a glimpse of a grey or bluish body cutting itself into the ground a few metres from them; a cow fell to the earth at a distance of 4.5 m. About one hour later they took the meteorite out of the pit, 30 cm. deep, it had formed. Its top was 2 cm. below ground. The soil is here dried up owing to drought, but is normally swampy and covered with grass. The fallen meteorite, weighing 2,250 gm., of irregular shape, with smoothed angular contours, scattered the earth 5 cm. from the edges of the pit, mostly in the eastern direction.

The Geological Institute of the Ukraine Academy of Sciences, Kiev, was informed of the fall, and on June 29, Souchtchitsky, a scientific worker of the Institute, took the meteorite to Kiev. At the Institute, Pilipenko, analytical chemist, obtained the following results by analysis of the meteorite.

	I	II	III	IV
Composition	Per cent	Relative Numbers	Relative Numbers	Per cent
SiO ₂	44.40	12.43	19.80	39.06
FeO	40.04	86.66	45.79	45.33
Al ₂ O ₃	2.21	0.23	0.62	1.73
MnO	0.003	0.04	0.02	0.05
Cr ₂ O ₃	0.54	0.19	0.20	0.45
MgO	7.89	—	—	6.23
CaO	2.51	—	—	1.61
S	2.68	1.23	2.47	2.77
NiO	traces	13.60	3.20	1.55
TiO ₂	—	0.12	0.06	0.018

The crust was taken off during the analysis (III totalling 1.75 gm.). The inner substance of the

meteorite was pounded in a mortar and the magnetic portion was isolated (II, total 2.46 gm.), as was the non-magnetic portion (I, 1.573 gm.). Column IV of the table shows the mean chemical composition of the meteorite as given by the director of the First Astronomical Observatory of Odessa, R. L. Dreizin, who inspected the place of the fall on August 26-31, 1938. I wish to express my gratitude for information provided by him.

The meteorite has small hollows or piezoglyphs. It is covered with a dull black crust; inside it is grey. The shepherds had broken off a small piece, which is lost, from one of the angles. Its shape is not orientated.

The direction of flight was approximately from south-west to north-east; the geocentric velocity was evidently very small (absence of light phenomena, loud detonations, crushing and deep piezoglyphs). The meteorite obviously fell as one stone. The position of the radiant, $\alpha = S. 30^\circ W.$, $h = 30^\circ$ for $14^h 07^m$ local time gives the equatorial co-ordinates $\alpha = 88^\circ$, $\delta = 2^\circ$, that is, 23° from the sun ($\alpha = 79^\circ$, $\delta = 23^\circ$). The apparent elongation from the apex is $\epsilon = 90^\circ$, the true elongation for a parabola is $\epsilon' = 143^\circ$, and the unperturbed geocentric velocity, $v_p = 10.8$ ($v_p' = 15.6$ km./sec.), which accounts for the weakness of the acoustic and optical phenomena.

The "Zhovtynsky" Meteorite, khutor Pavlovka, Mariinsky District, Stalino region, Ukraine. This stone meteorite fell on October 10, 1938, entering to a depth of 70 cm. into the ground. Its weight is 30 kgm. The fall occurred at night. Some days later it was found by a peasant, Maria Boushna. The meteorite was dragged out of the hole it made and broken into many fragments. At the break it is grey, stony, with metallic spangles. The greatest part of the fragments was taken to the Stalin Museum (at Stalino, Ukraine), four pieces were brought to the Academy of Sciences of the U.S.S.R., Moscow, to the Meteorite Commission. On December 16 another large piece was handed over to the Academy.

This meteorite is the fifth to be found in 1938 in the U.S.S.R. The total number of meteorites of the U.S.S.R.¹ is now (Jan. 1, 1939) ninety-five.

The Helm Wind of Crossfell

OCCURRENCES of 'helm wind' have been tantalizingly few; several have coincided with other engagements, or with serious difficulty in crossing the Pennines. It is established, however, that (a) the characteristic phenomena¹ are liable to occur whenever a well-developed current of air is flowing from a direction between east and north-north-east, that is, within about 30° of a direction at right angles to the trend of the escarpment. With deviations greater than this, considerable modifications are found to occur. (b) The depth of the surface air current up to the summit level of the clouds should be not greater than about 5,500 ft. The observed phenomena then appear to be analogous to those at a submerged weir with faces inclined gently upstream, and more steeply downstream. The 'helm wind' corresponds to the 'rapid' set up in the air-current flowing over the

escarpment; the crest of the downstream 'standing wave' is marked by the 'helm bar'. If the north-easterly current is of greater uninterrupted depth, the 'standing wave' appears to flatten out and the 'bar', with its underlying reverse current at ground-level, is no longer found.

Keen local observers therefore distinguish 'general north-east wind' from 'helm wind', and from the evening 'fell wind', a katabatic flow in quiet weather. As might be expected, the wind at the ground is characteristically very gusty near a point halfway between the 'helm cloud' and the 'bar', sometimes causing structural damage. The desiccating effect in spring near the escarpment may also be serious. With wind of force 8 at Tynemouth, the 'helm wind' may be expected to attain force 9 on open slopes; progress against it is not easy.

It is hoped that a reasonable explanation will soon be given of numerous local sayings and writings based on observation; the continuous record of temperature at 2,735 ft. should also be of interest.

These investigations have been carried out during the past year with the help of a grant from the Leverhulme Trustees.

Micro Separations by Chromatographic Adsorption on Blotting Paper

THE separation of mixtures on a micro scale by chromatographic adsorption was carried out as long ago as 1910 by Tswett, the discoverer of the process, and by various others since, but the method has not been applied as extensively as its extraordinary power would warrant. The preparation of the adsorbent column and the development of the chromatogram are troublesome and time-consuming operations and the process ordinarily comes under consideration only as a last resort. The purpose of this communication is to describe a simple and rapid method of effecting such separations which avoids entirely the difficulties inherent in the use of Tswett columns, and which, in addition, possesses distinct advantages of its own.

The technique consists essentially in the use of ordinary white blotting paper, or a suitable grade of filter paper, as the adsorbent medium. A sheet of the paper is placed between two pieces of plate glass (6 in. x 6 in. is a convenient size) one of which, the cover plate, has a small hole (3/16 in. or 1/4 in.) at its centre. A solution of the material under investigation is introduced through this hole, either dropwise or by means of a pipette with a capillary tip resting on the paper, and this is followed by the introduction of the developing solvent. Under these conditions, the components of the solution travel outward in concentric zones. The chromatogram is then obtained in a form which is particularly well suited to visual examination if coloured substances are present, or to examination by appropriate chemical or physical methods in the case of colourless substances. In addition, this type of chromatogram possesses the distinctive feature that it may be filed, after drying, for future reference. The paper being readily available, no extensive preliminary preparations are

necessary and the time required for an experiment is from three to five minutes.

The adsorbent characteristics of papers differ somewhat, but the choice of paper for this work will be governed rather more by other factors such as porosity, uniformity, and freedom from impurities. A thin and moderately hard blotting paper is more satisfactory in physical characteristics than filter paper of ordinary thickness, but it should be pointed out that many commercial white blotting papers contain a blue colouring matter which may give rise to spurious zones under certain conditions. The blotting paper made by the Eastman Kodak Co. for photographic purposes is fairly satisfactory in this respect.

It has been found that a surprising number of separations of various kinds can be carried out on paper, for although paper is not a particularly powerful adsorbent, what it lacks in this respect can very often be compensated by a suitable choice of solvents. There are, nevertheless, numerous problems in analysis by chromatographic adsorption which necessitate the use of a more powerful adsorbent. In order to retain the simplicity and convenience of the present method it would be desirable to secure for this purpose an absorbent paper impregnated with suitable adsorbing materials, particularly alumina. At the present time one may adopt the expedient of using a film of the powdered adsorbent between two sheets of filter paper.

As a lecture demonstration experiment the separation of the pigments of green leaves can be recommended. It is carried out most effectively on paper using a carbon disulphide solution of the pigments and using carbon disulphide also as the developing solvent. The brilliant colours of the carotenoid pigments together with the two chlorophyll pigments present a very striking display when resolved in this way.

The new method is not proposed as a substitute for the Tswett column when quantities of more than a few milligrams are to be treated. It is strictly a micro method, and as with the micro Tswett column the difficult problem of identifying the zones is constantly arising. However, it can be recommended as a useful adjunct to the Tswett column, as the task of finding by trial the most favourable conditions for a particular separation is greatly simplified. Attention is directed to the possibility of adapting the method to various problems in quantitative analysis, particularly where coloured substances are dealt with, and also to the possibility of its use, in conjunction with organic reagents, in qualitative inorganic analysis.

Lipæmia and Calcæmia in the Cock induced by Diethylstilbæstrol

Rats as well as chickens are transformed into eunuchoid dwarfs by prolonged treatment with oestrogenic hormone¹. During these experiments, a high degree of lipæmia was found in the chickens². The total blood fat can rise to 8,000 mgm. per cent (the normal being 100–200 mgm. per cent). The animals, the blood of which looks like cream, can finally succumb with dyspnoic symptoms to fat thrombosis of the pulmonary blood vessels, in

extreme cases. The internal organs, too, show considerable lipæmia. Thus, for example, the fat content of the liver can rise to 24 per cent of the dry matter (normal being 4.56 per cent). Lipæmia is found physiologically in the hen during the egg-laying season (increase from 100 mgm. to 580 mgm. per cent). In the cock, no spontaneous lipæmia occurs. Oestrogenic hormone, however, can induce lipæmia in the cock as well, dependent on the dose of hormone administered. Oestradiolbenzoate proved to be two and a half times as effective as oestrone. One dose of one mgm. oestradiolbenzoate is ineffective; two days' treatment, however, with 2 mgm. daily, certainly results in lipæmia on the third day (increase to 600–800 mgm. per cent). This lipæmia due to oestrogenic hormone is independent of nutrition, occurring likewise in fasting animals. In rodents (rabbits, rats), as well as in man, even prolonged administration of large doses of hormone does not induce lipæmia. This lipæmia represents the specific effect of oestrogenic hormone, since no effect is obtained either with cholesterol or with sterol-like hormones (we tested progesterone and testosterone).

During recent years, a number of synthetic substances having an oestrogenic effect have been discovered, the most active of which is the 4:4'-dihydroxy- α - β -diethylstilbene (diethylstilbæstrol), which was described by Dodds, Golberg, Lawson and Robinson in 1938³. This substance is able to initiate oestrus in ovariectomized rats, given in doses of 0.3–0.4 γ . Comparative tests show it to be between two and three times as potent as oestrone under similar conditions. After having ascertained that the production of lipæmia in the cock was due to the specific action of oestrogenic hormone, it was obvious that the question of whether this synthetic substance, which differs chemically from the oestrogenic hormone, was able to exert similar effects to those of the hormone, should be investigated.

0.5 mgm. of diethylstilbæstrol does not increase the blood fat, while 1 mgm. gives rise to an increase of 122–517 mgm. per cent. Two days' treatment with 4 mgm. respectively results in enormous lipæmia on the third day, the fat proportion increasing from 196 to 2,380 mgm. per cent. After six days' treatment with 24 mgm. of diethylstilbæstrol it increases from 125 to 5,438 mgm. per cent (cf. accompanying table).

Calcæmia. The striking changes of the bone structure¹ encountered in eunuchoid dwarf cocks lead to the conclusion that prolonged administration of oestrogenic hormone produces changes of the calcium metabolism. In fact, enormous calcæmia was found in those dwarf cocks². The calcium concentration in the blood of the cock is normally up

to 15 mgm. per cent, while it rises in the hen during the egg-laying season to as much as 26 mgm. per cent. In those cocks which had been treated with oestradiolbenzoate for a considerable period of time we encountered calcium values of so much as 55.3 mgm. per cent on an average. Lipemia and calcaemia follow parallel lines. Riddle and Dotti⁴ succeeded in producing calcaemia in animals through administration of oestrogenic hormone, the values increasing from 10 to 12-14 mgm. per cent. Such an enormous calcaemia as we succeeded in producing through administration of large doses of oestrogenic hormone has not yet been observed so far as we know.

The action of diethylstilboestrol is similar to that of oestradiolbenzoate. After 2 days' administration of 4 mgm. of diethylstilboestrol respectively, the blood calcium, in the cock, rises to 22.6 mgm. per cent. Subsequent to 6 days' treatment with 24 mgm. it is 41.4 mgm. per cent (cf. accompanying table).

The strong action of diethylstilboestrol also results from the fact that only two weeks after the first injection the cock's comb begins to shrivel and becomes anemic, while prolonged treatment produces loss of turgor and makes it drop.

The above investigations, therefore, demonstrate that diethylstilboestrol, like oestrogenic hormone, brings about lipemia and calcaemia in the cock, while being at least as effective as oestradiolbenzoate.

Pituitrin Anemia

Dodds and Noble¹ first described the severe anemia occurring in rabbits following parenteral administration of posterior pituitary extract. They considered this action of pituitrin a selective one on the cellular elements of the blood. We² confirmed the anemia caused by pituitary extract, but placed a different interpretation on the mechanism involved, for accompanying the anemia there was a marked fall in the osmotic pressure of the blood. We therefore believed that the dilution in the concentration of extracellular electrolytes resulted in a passage of fluid into the red cell with a subsequent rupture of the cell membrane. The reduced electrolyte concentration of the serum was considered to be the result of the powerful antidiuretic action of large doses of pituitrin. Also, the possibility that pituitary extract may promote the excretion of large amounts of electrolyte was considered.

Dodds, Liu and Noble³ take exception to the above interpretation on the basis of their studies of the water balance of rabbits following pituitrin injection. They observed that, although an oliguria resulted, the water intake of the injected animals also decreased. Therefore, it was concluded that rabbits were not in a positive water balance, and hemolysis could not have resulted from water retention.

The issue resolves itself into the relative value of an accurate determination of serum osmotic pressure versus an approximation of the water balance of a rabbit for determining the electrolyte environment of the red cell. The term approximation is used because the rabbit is a notoriously difficult species in which to determine water balance. The gastrointestinal tract of these animals is always filled with a semifluid chyme. Even if the inhibition of urinary secretion is exactly balanced by the diminished water intake, appreciable dilution of the serum occurs as absorption of fluid proceeds from the gastro-intestinal tract. Also it must not be overlooked that pituitrin causes the excretion of electrolyte as well as the retention of water. These two factors can combine to alter the osmotic pressure of the serum and cause extreme swelling of the blood corpuscles. It is our belief, however, that water retention is the primary cause for the alterations in blood chemistry.

In the experiments of Dodds and collaborators, blood volume determined by a method not mentioned failed to show any increase. We, on the other hand, measured serum osmotic pressure by the vapour pressure method of Hill⁴, one of the most sensitive of analytical procedures. We found the serum of the injected rabbits to be isosmolar with sodium chloride solutions of 0.64 per cent instead of 0.9 per cent which is normal. In one experiment the diminution in the concentration of serum electrolyte was so great that the serum was isosmolar with a 0.56 per cent sodium chloride solution. Dodds and co-workers, however, criticize these figures by an indirect approach which does not take into account the possibility of an internal water shift. We made note of the fact that the food intake and consequently the fluid ingestion of their experimental rabbits were markedly diminished. Nevertheless the reported changes in the serum electrolyte concentration did occur. Until it can be shown that severe pituitrin anemia can be obtained in the absence of any change in the electrolyte composition of the fluid medium of the red blood cell, we believe that the cause of this anemia is erythrocyte hemolysis resulting from water shifts and not the "agglutinating and hemolyzing" property of posterior pituitary extract on red blood corpuscles.

Phytic Acid and Mineral Metabolism in Poultry

THE possible parts played by phytic acid in the mineral metabolism of poultry have received surprisingly little study. Recently Lowe, Steenbock and Krieger¹ have directed attention to the significance of this subject, and have shown that, with diets where addition of phytin failed to improve calcification, the addition of the same amount of phosphorus as disodium hydrogen phosphate improved calcification.

A series of mineral metabolism experiments with pullets in progress in this laboratory lends strong

support to these observations. It has been found that pullets fail to hydrolyse a considerable proportion of the phytic acid present in their rations. Calcium carbonate supplements appear to lower the proportion hydrolysed, just as in the case of the rat¹. The experiments also suggest that when a ration is supplemented with calcium (a) in the form of carbonate and (b) in the form of tribasic calcium phosphate, a greater proportion of the phytic acid is hydrolysed in the case of the ration supplemented with calcium phosphate than in the case where the supplement is calcium carbonate.

It is also clear from the experimental results secured to date that the conclusions of Knowles, Watkin and Hendry² with regard to the nature of the calcium and phosphorus compounds present in the excreta of the domestic fowl require modification, in so far as a considerable proportion of the phosphorus excreted by pullets on rations similar to those used by these workers is in the form of phytic acid phosphorus. Furthermore, while the rule found by Knowles, Watkin and Hendry³ with regard to the ratio of 'non-carbonate calcium' to total phosphorus in the excreta has been verified in the case of non-laying pullets, it does not appear to hold for the excreta of laying pullets, even when the excreta contain appreciable amounts of carbonate.

It is hoped to publish a fuller account of these experiments at a later date.

A Metabolic Explanation for Irritation and Coma Produced by Rise in Intracranial Pressure

INCREASE in pressure inside the cranial cavity, whether local or general, first produces symptoms of cerebral irritation such as convulsions, contraction of the pupil, vomiting and rise of blood pressure, and is followed by coma, dilatation of the pupil, and other symptoms of paralysis of the nerve centres. The current explanation for this train of symptoms, which is seen in many pathological processes (for example, intracranial hæmorrhage, oedema, tumour, etc.), supposes that irritation is caused by congestion of the cerebral vessels and cyanosis, while further increase in pressure produces profound cerebral anæmia and coma.

The first result of a rise in intracranial pressure is to cause partial collapse of the venous sinuses of the dura mater and of the cerebral veins¹, accompanied by a diminution in the rate of venous return. Accordingly the rate of oxygen supply to the brain is much diminished and approximately anaerobic conditions are realized in some of the cells. Now, it has been shown that under anaerobic conditions the rate of katabolism of glucose by cerebral cortex is enormously increased². Thus the rate of catabolism of glucose by rabbit's cortex has a low value in oxygen ($Q_{O_2} = -8$), whereas in nitrogen this quotient is increased manyfold ($Q_{N_2} = -8$). Recent observations which I have made on the metabolism of human cortex (kindly given to me by Mr. McConnell of the Richmond Hospital, Dublin)

indicate that here anoxæmia has essentially the same effect in increasing metabolism. Thus the Q_{O_2} of human cortex, calculated from measurements of respiration and glycolysis, is -8 in oxygen and -10 in nitrogen. This stimulation of metabolism may well be accompanied by stimulation of the nerve centres, and thus convulsions and other symptoms of irritation are really due to the intracerebral anoxæmia, which is itself the result of rise in intracranial pressure. Still further increase in intracranial pressure causes capillary collapse and so seriously impedes the cerebral circulation as to deprive the brain cells of glucose, their main metabolic substrate. The rate of cerebral metabolism is now substantially diminished even below its normal level, and irritation thus gives place to paralysis. In this manner, a progressive rise in pressure within the cranial cavity may first produce a stimulation of metabolism associated with irritation, and is later followed by diminution or even cessation of metabolism, accompanied by coma and other terminal symptoms of compression.

The convulsions produced by heart block in man and by ligation of the carotids and vertebrals³ in animals have probably the same cause as those produced by rise in intracranial pressure. In these cases also, anoxæmia causes increase in katabolism of sugar by the brain cells with increase in nervous irritability. Further, Loewenhardt, Lorenz and Waters⁴ have found that intravenous injection of sodium cyanide causes stimulation of the respiratory centre and also a remarkable cortical stimulation in stuporous cases of dementia præcox. They suggest that the cyanide, by inhibiting oxygen absorption, stimulates anaerobic metabolism. Stone⁵ also has shown the lactic acid content of brain increased by cyanide convulsions and suggests that convulsions may be associated with increased tissue activity. I have found the Q_{O_2} of rabbit's cortex, as above calculated, to be increased from -2 to -7 by the addition of $2 \times 10^{-3} M.$ sodium cyanide. The respiration is simultaneously diminished by 50 per cent, but the aerobic lactic acid production is markedly stimulated. Here again increased nervous activity is connected with increase in katabolism of glucose.

Proteins of Rattlesnake Venom

RECENTLY, Slotta and Fraenkel-Conrat^{1,2} reported that they have succeeded in separating the whole of the neurotoxin and hæmolysin of *Crotalus-torridus* venom in a crystalline form, and that repeated recrystallization of this substance did not change its physiological properties or its chemical composition. This crystalline substance containing both neurotoxic and hæmolytic activities was considered by them to be a pure substance. In the course of our investigation on the separation of the various active principles of *Crotalus-torridus* venom, we have found that the hæmolysin can be partially separated from the neurotoxin by adopting the following procedure:

100 mgm. of venom was dissolved in 10 c.c. water

and its pH adjusted between 7.0 and 7.2. The solution was then saturated with sodium chloride and left overnight inside a refrigerator at 6° C. The next morning the precipitate formed was separated by centrifuging and washed once with saturated sodium chloride. This precipitate was found to contain 8-10 per cent of the total hæmolytic activity and only 2-2.5 per cent of the total neurotoxic activity of the original venom. Thus the percentage ratio of hæmolysin to neurotoxin has a much higher value, 4:1, in the precipitate we obtained, than it had in the original venom. It is evident, therefore, that the hæmolytic and neurotoxic activities of *Crotalus-t-terriflous* venom are due to two different substances. Hence the crystalline substance which Slotta and Fraenkel-Conrat obtained was not a pure protein, but a mixture of at least two different proteins. In this connexion, it may be mentioned that we have succeeded in separating the hæmolysin completely from the neurotoxin of *Naja Naja* venom as reported elsewhere*.

We wish to thank the Indian Research Fund Association for a grant for continuing this work.

The Prehensile Paw of the Giant Panda

There is little to be said in answer to Prof. Wood Jones's remarks on this subject¹; but I can assure him I overlooked neither of the facts he thinks I did. I gave him the credit for the interesting discovery, previously only an inference from what was known of the skeleton of the foot, that the sesamoid bone in question has a special muscular arrangement whereby it can be moved.

Possibly I should feel gratified by his confirmation of my statement that the grasping method of the panda's fore paw is strictly comparable to that effected by closing the tips of the first and second fingers on the ball of the thumb in the human hand. It is unfortunate that in his first account he conveyed the idea that the method is equivalent to that exercised by the entire thumb. Without reservation and without fear of admonition from anyone acquainted with the undivided paw of this animal, I adhere to my assertion that his description was misleading; and I venture to predict that wisdom will forbid its repetition in his final treatise on the subject.

Points from Foregoing Letters

HAVING obtained the vacuum spark spectrum of iron, Dr. L. S. Bowen and Dr. B. Edlén have determined the wave-lengths of the forbidden transitions between the terms of the $3d^2$ levels, and find that these lines correspond to the lines of hitherto unknown origin in the spectrum of Nova RR Pictoris (1925).

Assuming the existence of inhomogeneities and thermal currents in the earth's core, Dr. W. M. Elsasser calculates that temperature differences so low as 10° would give rise to currents whose irregular distribution may result in a small one-sided excess that would account for the earth's magnetic field.

Dr. G. Gamow and Dr. E. Teller, in reply to Sir James Jeans's criticism of their hypothesis of the origin of nebulae, point out that most of the objections raised would not affect the order of magnitude of their calculated result. An important difference in the value for the mean density of matter arises, however, if one accepts Sir James's assumption that the so-called clusters of nebulae are stable, rather than that the nebulae themselves are in a state of equilibrium, as supposed by the authors.

The usefulness of synthetic lithium fluoride crystals as optical material owing to its transparency to wave-lengths from 1200 Å. up to 20,000 Å., is stressed by B. K. Johnson, who states that he has designed a lens system combining lithium fluoride and fused quartz, which should give complete achromatism for a spectral range between 5461 Å. and 2749 Å.

A simple method for the micro-separation of the components in a mixture by capillary adsorption on filter paper is described by Prof. W. G. Brown.

Diethylstilboestrol, like oestradiolbenzoate and oestrone, increases the fat and calcium concentration in the blood of the cock, and eventually causes the loss of the comb, according to Prof. B. Zondek and L. Marx.

Prof. A. Gilman and Prof. L. Goodman claim that their explanation of the anaemia produced in rabbits by administration of posterior pituitary extract, being due to the fall in the osmotic pressure of the blood, are more likely to be correct than the results obtained by Dodds and collaborators based upon the "water balance" of rabbits.

Experiments reported by Dr. R. H. Common indicate that when phytin alone is added to the diet of pullets they fail to utilize it completely. Calcium phosphate, if added, increases the proportion of phytin hydrolysed to a greater extent than does calcium carbonate.

In the absence of oxygen, the katabolism of carbohydrate by both rabbit and human cerebral cortex is increased. Dr. K. C. Dixon suggests that the convulsions and cerebral irritation which follow rise in intracranial pressure and other processes producing cerebral anaemia, are due to this increased metabolism of the brain cells associated with stimulation of the nerve centres.

Dr. B. N. Ghosh and S. S. De describe a method for the partial separation of the hæmolysin in the venom of *Crotalus-t-terriflous* from the accompanying neurotoxin and point out that the crystalline substance prepared by Slotta and Fraenkel-Conrat, possessing both these properties, is probably a mixture.

Research Items

Anthropometry of the Ovimbundu, Angola

IN the course of the Frederick H. Rawson Field Museum Ethnological Expedition to West Africa, measurements were obtained of 53 adult male Ovimbundu, which, though an inadequate sample, are valuable owing to the paucity of material from Angola. There are, it is believed, no other measurements of the Ovimbundu available for comparison. This material has been studied by W. D. Hambly, of the Field Museum of Natural History, Chicago (*Publication 426, Anthropological Series*, 25, 2; 1938). In skin colour all were brown, and only four approached black, which four might be described as 'light brown'. All eyes were dark brown, and the hair was typically Negro. Facial hair was sparse. The standing height averaged 1687.1 mm., just within the tall class. The average length of the head is 187.3 mm. and the breadth 136.8 mm., with an average cephalic index of 73.1. The average head height is 135 mm. The cranial capacity (Pearson's formula) is 1370 c.c. The facial index is 93.7 and the average nasal index 87.9, just within the platyrrhine group. Measurements on the nose show high variability, 35.8 per cent being mesorrhine, 58.5 per cent platyrrhine. Only 5 per cent are hyperplatyrrhine, with an index of 100+. In regard to variation, head-breadth stands first in constancy of measurement, while head-length is almost as constant. The cephalic index also has a low variability. In comparison with other tribes of Angola, the Ovimbundu are not greatly removed in stature from the man of eastern Angola; but they are decidedly more long-headed and mesorrhine. The differences may be due to fixation of type owing to isolation. The Ovimbundu are known to have built up a strong confederacy. Compared with negro tribes outside Angola, the general build and physiognomy, together with the nasal index, suggest a contact, perhaps remote in time, with the north-east African element described as Hamitic.

Cyanide in the Determination of Ascorbic Acid

M. Cushman and A. M. Butler (*Proc. Soc. Exp. Biol. and Med.*, 39, 534; 1938) review the literature and present further evidence concerning the effect of potassium cyanide on 2,6-dichlorophenolindophenol, the stability of ascorbic acid in whole blood, plasma and plasma filtrate, and the question whether potassium cyanide should or should not be used with plasma ascorbic acid determinations. Their conclusions were as follows: The use of potassium cyanide does not necessarily invalidate the results and may cause no error. Certain lots of potassium cyanide may decolorize 2,6-dichlorophenolindophenol, the decolorizing power of a particular lot depending upon the concentration of the salt and the pH of the dye-salt solution. Reduced ascorbic acid is stable in whole blood or metaphosphoric acid filtrates for so long as 24 hours. There is a significant loss of reduced ascorbic acid when plasma stands at room temperature for more than four hours. The loss is not prevented by the presence of potassium cyanide. There is therefore no reason for the addition of potassium cyanide in the determination of plasma ascorbic acid.

pH Stability of Elementary Bodies of Vaccinia

J. W. Beard, H. Finkelstein and R. W. G. Wyckoff (*J. Immunol.*, 35, 415; 1938) determined the pH range of infectiousness of purified suspensions of the elementary bodies of vaccinia in rabbits by titration. The infectiousness was found to be most stable between pH 4.5 and 10. On the acid side, inactivation was immediate below 2.5 and on the alkaline side above 11.5. In the analytical ultracentrifuge, purified active suspensions gave a single fairly sharp boundary with the sedimentation constant $S_{20} = 5400 \times 10^{-13}$ cm. sec.⁻¹ dynes⁻¹. The elementary bodies became lighter and hence were broken down at those pH values at which they were immediately inactivated. The iso-electric point was determined to be between pH 4.3 and 4.6.

Cross-beaked Fowls

THE cross-beak condition is normal in the widely distributed genus *Loxia* and the endemic Hawaiian genus *Loxops*. In *Loxia* a straight beak occurs as a rare abnormality, while cross-beaked specimens have been recorded in many different genera and species of birds. In zebra parakeets the condition occurs repeatedly, and it has frequently been reported in domestic fowls. Dr. Walter Landauer (*J. Genetics*, 37, No. 1) has studied cross-beak in silver spangled Hamburgs, White Leghorns, Rhode Island Reds and Dark Cornish Fowl as well as other breeds. He finds that, in *Loxia* as well as the commonest type of cross-beak in fowls, the beak is normal at hatching and begins to be crossed later. In both, the beak may deviate to the right or the left side; but the condition is more variable in fowls than in *Loxia* and may involve either beak, whereas in *Loxia* it is always mainly in the lower beak. Four different types of cross-bills have been observed in chickens. Type I is associated with eye defects, Type II is found among homozygous embryos of Creeper and Japanese Bantam, Types III and IV are hereditary, the former appearing in the second month of life and the latter before hatching. In these hereditary types the upper beak is generally involved. The breeding results suggest that the genetic basis is complex in both cases. No individuals breeding true for cross-beak were obtained, and crosses between Types III and IV gave only normal offspring. A fifth type of cross-beak appears to be associated with polydactyly.

Relationships of the Fish-Hawk or Osprey

AT various times and by various authors the osprey has been regarded as most closely related sometimes to the eagles and sometimes to the kites; but the linkage has been indefinite because most of the characters used in the classification of the osprey have undergone so much adaptive modification as to be unreliable. Lawrence V. Compton, after a thorough analysis of the feather tracts (pterylosis) of the hawks, concludes that the arrangement of the tracts affords evidence of taxonomic value (*Univ. California Pub. Zool.*, 42, 173; 1938). The characters afforded by feather tracts divide the hawks into three natural groups: the Accipitrid type, the Falconid type, and the Cathartid type. The secretary bird may represent

a fourth group, although it is more closely related to the accipitrids than to the other hawks. The osprey (*Pandion*), according to its feather groupings, is most closely related to *Cathartes*, and not to the falcons, with which it has usually been placed. But its characters are sufficiently distinct to warrant its separation in a family, Pandionidae, equivalent in rank to the family Cathartidae, within the sub-order Cathartae.

Sexual Reproduction of *Ranunculus Ficaria*

It is known that *Ranunculus Ficaria* seldom sets viable seed, and C. R. Metcalfe has shown that of the two forms, namely, those with and those without aerial tubercles, the latter invariably produce a higher proportion of viable seed. The author has recently made a full investigation of this phenomenon (*Ann. Bot.*, New Series, 3, No. 9, 91; 1939). He has shown that lack of viable seeds is due chiefly to certain forms of degeneration in either the embryo-sac or the nucellus. These forms of degeneration are described. It is also shown that ovules frequently become disorganized even when active pollen tubes are present; therefore degeneration cannot be due to the lack of viable pollen. Fertilization is not essential to the formation of endosperm in normal embryo-sacs, and proof was obtained that embryos sometimes arise apomictically from unfertilized eggs. Reasons are also stated why seed which is apparently viable is not always capable of germination.

Floors for Industrial Purposes

AN account of the work done in connexion with the many problems concerning floors for industrial purposes was given by R. Fitzmaurice and F. M. Lea, of the Building Research Station, before a joint meeting of the Institution of Structural Engineers and the Institution of Chemical Engineers on January 26. It was pointed out that comparative test data on the relative resistance of various materials to impact and abrasion are practically non-existent and indeed a satisfactory discriminating test has not yet been devised. The authors gave a rough classification of the usual conditions of abrasion and of the types of flooring materials in common use in the different conditions quoted. When chemical action is added to the mechanical agencies of destruction the case is more serious. There are many substances the action of which on concrete is so slow and so limited that they have been successfully stored in concrete tanks; but when assisted by abrasion on a concrete floor they give a great deal of trouble. The authors also gave details of the floor conditions found in several groups of factories in typical industries. It was pointed out that volume changes caused by variations of moisture content give a good deal of trouble as the cracks allow corrosive liquids to penetrate to the structural floor beneath, and in this connexion the authors gave data of the amount of shrinkage in the principal materials and offered some valuable suggestions for its mitigation. They also dealt with some points in relation to the structure. One of these had reference to the provision of continuous slabs extending over several beams. The reversal of the bending moment requires that the reinforcement be brought to the top. If now a top dressing is applied to the slab, the reinforcement is no longer in the right place to resist the tensile stress, and cracks occur. It is recommended, therefore, that a joint be made in the concrete finish or that additional reinforcement be provided in it.

Isotopes of Uranium and Lead

THE isotopic constitution of uranium and lead has been studied by A. O. Nier (*Phys. Rev.*, 55, 150; using a mass-spectrograph. The positive ions of these elements were produced by vaporizing salts of the metals and bombarding the vapours with electrons. Uranium from several different ores gave the isotopes U^{238} , U^{235} (abundance ratio $U^{235}/U^{238} = 1/139$) and U^{234} (abundance ratio $U^{234}/U^{238} = 1/17,000$). No other isotopes were found. From the abundances of these elements the decay constants of U^{238} (UI), U^{235} (AcU) and U^{234} (UII) were found. The lead from twenty-one sources was similarly examined. The isotopes of uranium lead Pb^{206} , Pb^{207} , of common lead Pb^{208} , Pb^{207} , Pb^{206} , Pb^{204} , and of thorium lead Pb^{206} were found. The abundances of the isotopes agreed in general with the chemical atomic weights which have previously been used to distinguish the proportions of the different leads. The ratio between the abundance of lead from the Ac and U series (Pb^{207}/Pb^{206} corrected for common lead contamination) provides a new method of estimating the ages of minerals, and it is possible that the method would give results more reliable than the well-known determination of the Pb/U ratio in cases where the mineral has been subject to alteration. It is shown that it is very unlikely that Pb^{206} decays to Pb^{204} , as has been suggested.

Testing of Transmission Line Insulators

It is known from the annual reports on atmospheric pollution, issued by the Department of Industrial and Scientific Research, that in London and other large cities, solid deposits settle from the atmosphere at an average rate of about one ton per day per square mile. As a rule, these deposits consist of free carbon and metallic salts in various proportions. Sometimes they settle on high-tension transmission lines and on the insulators supporting them. When dry, such deposits have a comparatively high electrical resistance, but when moist the salts go into solution and the resulting damp deposit is a much better conductor. The outdoor insulators used on overhead power lines are exposed to these deposits and trouble is sometimes experienced with them causing flash-over and dangerous surges of electricity along the wires. Near the sea coast in Great Britain, both salt and industrial deposits present serious problems. In an important paper read by W. J. John, of Queen Mary College, and C. H. W. Clark to the Institution of Electrical Engineers, on February 15, this problem has been very successfully attacked both in the laboratory and in the open air. In the first case, an aeronautical wind tunnel was used through which air was drawn by a fan, the salt-spray formed by an atomizer surrounding the insulator under test, and the way in which dew was deposited on it was noted. A high-pressure supply of 33 kv. was sometimes employed and oscillographic records of the leakage surface currents were obtained. In the outdoor tests, it was found that in average good weather conditions conductance is not a measure of the deposit on the insulators used in practice, as their edges and ribs remain clean and have a high resistance. Bad weather conditions which lead to flash-over in service are fog, mist, dew and frost. On several occasions rain was accompanied by mist, and this constituted as a rule the most serious weather conditions.

The Widmanstätten Structure of Octahedral Meteoric Iron

By Prof. S. W. J. Smith, F.R.S., and J. Young

THE effect known as the Widmanstätten structure is shown most clearly in those meteoric nickel-iron alloys in which the percentage of nickel lies between certain limits, roughly, from 7 to 14. When the percentage of nickel is less than about 6.5, there is no Widmanstätten structure—the single component is known as 'kamacite'. With higher percentages of nickel, there is always an additional component—known as 'taenite'. Attempts to find its percentage composition by chemical methods led to very different results, ranging from about 25 to 37—although in one isolated case a percentage of about 47.8 was recorded. These widely varying results are due to the difficulty of isolating the taenite from the kamacite with which it is so intimately mixed and indeed often encloses. It was for this reason that it occurred to one of us to attempt to determine the composition of the taenite *in situ* by means of 'thermo-magnetic' analysis (*Phil. Trans.*, A, 1908).

For various reasons these early efforts were not so successful as they might have been. Later it was possible, in Birmingham, to repeat these experiments with more suitable meteorites than that originally examined and to add micrographic and X-ray measurements to this method of attack. For the results obtained by the latter (*Proc. Roy. Soc.*, A, 1926, etc.), one of us (J. Y.) has been almost entirely responsible; while Mr. A. A. Dee gave valuable help in the development of the former.

Of the various octahedrites examined, the Butler meteorite, containing about 10 per cent of nickel and relatively free from impurities such as phosphorus, gave the most satisfactory results. It showed in the clearest possible way that the taenite has a reversible magnetic transition temperature at about 500° C. and therefore contains approximately 50 per cent of nickel. From the way in which it forms (see below), it is unlikely that a taenite band is of uniform composition. It may be sensibly less rich in nickel at its centre than at its boundaries. In any event, the thinnest bands are most likely to be of nearly uniform composition and to give the closest approximation to the equilibrium percentage of nickel in the γ phase alloy.

In agreement with this consideration, X-ray analysis shows that the narrowest taenite bands contain the highest percentages of nickel—about 55 per cent in these and about 50 per cent in the broader bands. It does much more than this. It shows that kamacite and taenite are, apart from impurities, solid solutions of nickel and iron—the former having a body-centred and the latter a face-centred cubic lattice. The lattice parameters confirm the inference from the thermomagnetic experiments regarding the composition of taenite. Other results are particularly significant. They show that the majority of the taenite crystals have a single orientation throughout the meteorite, their {111} planes lying nearly parallel to the kamacite-taenite lamellae. The kamacite crystals show small random deviations from the twenty-four orientations of the type; (110) kamacite parallel to (111) taenite, [001] kamacite inclined at 4° to [011] taenite. These relationships

hold in both band and plesitic structures; but the deviations are greater in the latter than in the former.

A significant feature of the taenite bands, revealed by micrographic investigation, is that only the narrowest of these consist entirely of γ -phase alloy. The central regions of the broad bands often show that an independent γ - α transition, sometimes described as 'plesite', has developed there. A characteristic feature of this development occurs where it meets the inner boundary of its taenite envelope. This boundary has a 'jagged' or serrated appearance—due no doubt to the conditions under which the last of the γ - α transition occurs. It exhibits the traces on the surface of rational planes of the taenite containing a [110] axis, such as {111}, {100}, {110} and {211}.

One of the most interesting problems presented by the results is the magnetic behaviour of the taenite, which would have shown little, if any, magnetic evidence of its existence during the first heating experiments if a step-by-step method of heating to successively higher temperatures had not been used. X-ray analysis provides an explanation of this phenomenon. It reveals the existence in the meteorite 'as received' of a transition layer at the taenite-kamacite boundary in which the lattice spacings of planes parallel to that boundary vary continuously from that of the {111} plane of the taenite to that of the {110} plane of the kamacite. This transition layer is that at which the last of the γ - α conversion occurs as the temperature falls. It would seem that it is the effect produced by the heat treatment upon this layer that enables the taenite to exhibit its ferromagnetism.

Very suggestive results were obtained from a study of an artificial nickel-iron alloy containing 10 per cent nickel cooled slowly from the molten state. Magnetic and X-ray analysis of this alloy showed that it consisted entirely of body-centred crystals. When, however, the alloy was heated progressively to, and annealed at, a temperature of 580° C., its subsequent behaviour indicated the presence of a γ -phase alloy containing about 30 per cent nickel. X-ray examination confirmed the presence of γ -crystals having a strongly preferred orientation, in which their {111} planes were parallel to the Widmanstätten figures in each grain, as in the meteorites. The α -crystals also exhibited twenty-four orientations differing little from those found in the octahedral meteorites. Although cooling in liquid air transformed some of the γ -phase into α , this is the nearest approach we have yet made to a reproduction of the essential features of an octahedral meteorite. Recent experiments by others support the view that a much closer reproduction would have been made by exceedingly slow cooling.

An interesting effect of the heat treatment of meteoric iron is the formation of slip planes in the taenite. These can be produced, for example, by heating to 650° C. followed by cooling in liquid air. Slip planes of the forms {111}, {100} and {110} are common and the direction of slip, when identified,

is [110]. There can be little doubt that such slip planes arise as a result of the differential contractions of the constituents when cooled and of the expansion associated with the γ - α -transformation when it occurs.

Finally, it may be of interest to summarise our views regarding the origin of the Widmanstätten structure in meteorites. It seems highly probable now that the kamacite lamellae are the result of a γ - α -lattice-mechanical transformation. This is shown by the relationship between the orientations of the kamacite crystals and the single orientation of the taenite, and is confirmed by the fact that approximately the same relationship is found in the 10 per cent artificial alloy in which the γ - α -transformation is known to have occurred.

As is commonly held, it is quite probable that

meteorites have originated during extremely slow cooling inside some massive heavenly body. In these circumstances, the lattice-mechanical transformation may have taken place so slowly that almost perfect equilibrium has obtained. From this point of view the parameter measurements of the taenite are significant—showing that the narrowest taenite bands are always richer in nickel than the broader ones. It would seem that the latter, owing to their thickness, cannot attain complete equilibrium at the lowest temperature at which effective diffusion is possible.

Acknowledgment of the contributions of many postgraduate students to the work, here outlined very briefly, will be made elsewhere. It is the fault of one of us (S. W. J. S.) that it is so much overdue.

Dimensions of Some Organic Molecules

THE forty-fourth Bedson lecture was delivered by Dr. J. Monteath Robertson to the Bedson Club at King's College, Newcastle-upon-Tyne, on January 27.

Under the title "The Dimensions of Some Organic Molecules", Dr. Robertson dealt with advances in this field, which have occurred mainly as a result of X-ray crystallography. A crystal may be regarded as a periodic structure of units containing electrons, which diffract X-rays, and from a consideration of the direction of diffracted beams, it is possible to determine the distance between these units. By a more involved analysis of the intensities of the beams, something may be learnt about the distribution of the electrons within the diffracting units, and from this, the structure of organic molecules can be investigated. The results are worked out as a two-dimensional graph of electron density, and although in general there is foreshortening owing to the molecule lying at an angle to the plane of projection, it is possible, by taking a series of projections, to obtain a true picture of the molecule in space. Upon such graphs, atoms, except hydrogen, the scattering power of which is insufficient for separate resolution, are clearly seen as circular regions of high electron density, and the peak values enable the separate atoms to be named. As a general rule, it is not possible to obtain the electron density graph without some assistance from chemical evidence, although in some cases the assistance is slight.

The results obtained may be classified under two heads; first, the qualitative confirmation of organic structures, and the refinement offered by the actual measurement of bond distances, and secondly, the information obtained with regard to the relative orientation and distance apart of the separate molecules in the crystals.

Bond measurements of organic compounds which can be represented by a unique structural formula show certain definite regularities. Both single and multiple bonds are constant in length, the atoms being nearer in multiple-bonded compounds than in single, and nearer in the case of nitrogen atoms than in the case of carbon. Bond distances between carbon and nitrogen atoms are the mean of the corresponding carbon-carbon and nitrogen-nitrogen distances. These regularities are not found where resonance is possible.

In such cases, the length of a single bond may have any value intermediate between those normal for single and double bonds. In some of the simpler cases it is possible to estimate bond distances by wave mechanics, and their actual measurement provides a very important check upon these highly involved theoretical calculations. Such measurements also played a very important part in the development of the theory of resonance.

With regard to intermolecular distances in crystals, we may also distinguish two groups, normal and abnormal. In the first, typified by the hydrocarbons, the molecules appear to be arranged in the most convenient manner, without any particular order, and the distances of nearest approach are of the same order for a great many compounds. In such substances as benzoquinone, as might be expected, the dipole causes some approximation of oppositely charged atoms, but the distance of nearest approach is not greatly reduced. In the second group (abnormal), the approach distances are less by nearly an angstrom unit, and this applies generally to those compounds which are known to be associated in the liquid or gaseous states. In the case of resorcinol, for example, very drastic changes are found. The molecules are orientated so that the hydroxyl groups come much nearer to each other than is normal. The structure itself, however, remains open, as is shown by the fact that resorcinol is less dense than benzoquinone. This indicates the strongly directive power of the intermolecular hydroxyl 'bonds', which can maintain such an open arrangement. However, when resorcinol is heated above 74° C., thermal agitation destroys this structure, the molecules are arranged without reference to the affinities of the hydroxyl groups, and the density rises. The higher temperature form takes several weeks to revert to the other, and can be studied in the usual way, when it is found that the molecules are arranged in much the same way as in a hydrocarbon crystal. The close approach of hydroxyl groups is very common, and in the case of hydrated oxalic acid, for example, it is thought that intermolecular resonance occurs.

In conclusion, Dr. Robertson said his intention had been to show that the newer developments of X-ray crystallography enable a definite and accurate picture of the molecular structure to be obtained.

Meridian Astronomy

ON February 10, Dr. H. Spencer Jones delivered his presidential address at the Royal Astronomical Society on "Meridian Astronomy". He pointed out that the purpose of meridian astronomy is to provide a fundamental system of reference, and this is defined by the positions and proper-motions of a network of stars distributed with reasonable uniformity over the whole sky, together with the numerical value of the constant of precession. There are difficulties in the exact determination of the equator—the plane of reference—and also of the equinox—the zero point—because observations of the sun, which are used to fix these, are liable to personal errors of a systematic nature.

These latter have been reduced very considerably by the use of the impersonal micrometer in place of the hand-tapping method. A moving wire is traversed across the field at such a rate that it moves with the object under observation, and contacts are automatically closed when the moving wire reaches certain positions in the field. Personal errors in the observation of stars by the hand-tapping method could amount to a few tenths of a second, but the impersonal micrometer has reduced these to a few hundredths of a second.

Although the bright inner planets can be used for fixing the equator and equinox, the perceptible diak and phase present difficulties, and the results are unsatisfactory. The suggestion of Sir Frank Dyson that Vesta should be used to determine corrections to the equator point and equinox has much to commend it, as this minor planet has a star-like image and is observed at night, and, in addition, is sufficiently bright for observation with the impersonal micrometer. Plans have been developed for utilizing a large number of minor planets to control not only the equinox and equator point, but also errors of a systematic nature.

It is remarkable that, in spite of great improvements in the design and construction of instruments, modern catalogues of stars still show systematic differences, especially in declination, and some interesting light is thrown on the problem by the new reversible transit circle, recently provided at Greenwich. A full description of certain discordances is given, and these were sufficiently large to enable the source of the trouble to be detected. One defect, *inter alia*, may be referred to. The guiding rod, along which the frame carrying the moving wire was constrained to move, was slightly convex to the eyepiece, and the guiding slide of the tailpiece which prevented motion in a direction perpendicular to the plane of the frame formed a constraint. The removal of small amounts of metal rectified these defects, and the lag of the moving wire behind the micrometer screw is now negligible.

Determinations of the precessional constant have usually involved the assumption of random distribution of stellar motions, but the existence of two star-streams, postulated by Kapteyn, Lindblad and Oort's theory of a rotating galaxy, and Schwarzschild's view of a preferential direction of motion, are not in accordance with the assumption. In consequence, the value obtained for the precession will depend upon the assumptions that are made, and, to avoid this difficulty, it has been suggested that the distant galaxies should be used as a system of reference. If the positions of a large number of the distant galaxies were determined with reference to neighbouring stars, the positions of the latter being directly related to the fundamental star system, a means would be provided for correcting and controlling that system and also for determining the constant of precession more exactly. Here is a work for the future that promises to be of assistance for meridian astronomy.

Brittany and Britain: Prehistoric Relations

DR. R. E. MORTIMER WHEELER'S lecture on his exploration of archaeological sites in Brittany last summer, which was delivered before the Society of Antiquaries of London on February 23, gave details of an investigation of which the results have been awaited with no little interest.

It will be remembered that the expedition which he described was undertaken on behalf of the Society of Antiquaries, with the support of the Leverhulme Trust and the University of London, and with the co-operation of the French authorities; and that it had as its specific object to probe the origins of the civilization, which Dr. Wheeler's excavations at Maiden Castle in Dorsetshire, and recent evidence from other sources, had shown makes its appearance with some abruptness in south-west Britain, evidently from foreign sources, in the century immediately preceding the Christian era. One of the more striking characteristics of this civilization is the adoption of what is here a new method of defence on a fortified

site—multiple lines of outworks, instead of the single line of ditch and rampart universal hitherto on the Wessex Downs, and manifestly designed to meet a new weapon of attack, the sling, to the use of which the multitude of sling stones for attack and defence now bears witness.

In seeking the place of origin of this innovation, the natural line of inquiry is directed towards the opposite shores of Brittany; but Dr. Wheeler found to his surprise, on making a survey of the material of the period both in northern Brittany and in north-west Normandy, that two camps only were at all comparable to Maiden Castle. Of these one is at Huelgoat, near Morlaix, the other Le Petit Cailand, near Avranches, on the Bay of Mont St. Michel. At the former, the work known as Le Camp d'Arthus was found to be of two closely related periods, dating approximately from the middle of the first century B.C. The 'Gallo' method of construction of the rampart, as described by Caesar, and the infertile

country around point to a military or political occupation, rather than one of economic significance. It was, Dr. Wheeler concludes, a military rallying post for the peoples of the surrounding country, the Oesimii, at the time of the Roman conquest. This conclusion is supported by the examination of the camp at Le Petit Celland, where the Gallic ramparts were never completed, but were destroyed by military action at a date indicated by coins of local type to coincide in time with Caesar's campaign.

Interesting as were these discoveries, they had provided the expedition with no analogy with the complex forts of the Wessex Downs; and its activities accordingly were then directed to southern Brittany. Here on the jagged cliffs, the bays, and wooded estuaries from Douarnenez to the mouth of the Loire, the home of the Veneti, Caesar's strenuous and

troublesome opponents by land and sea, are situated more than three fourths of the fortified works of this period in north-western France. Wherever in this region digging has taken place, multiple ditches and quantities of sling-stones have appeared. "Here, and here only", to quote Dr. Wheeler, "are the true forerunners of those tumultuous defences of South-Western Britain, in which the present research originated"; and in the name of the type camp excavated, Kercaradec, he is reminded of the familiar Shropshire Caer Caradoc. Dr. Wheeler goes on to suggest that as a result of the defeat of the Veneti in Caesar's campaign of 56 B.C., a remnant escaping from Roman vengeance for rebellion may have escaped to settle in Britain, following the earlier route already familiar to traders and prospectors who, there is evidence to show, had made their way to Cornwall.

Forest Types in India and Burma

IN a prefatory note to his monograph entitled "A Preliminary Survey of Forest Types in India and Burma" (*Ind. For. Rec.*, N.S. 1, No. 1, Govt. Press, Delhi, 1936), Mr. H. G. Champion, sylviculturist at the Dehra Dun Forest Research Institute, defines the purpose of the work. From the point of view of the average forest officer in India, Gamble's "Manual of Indian Timbers" and Brandis' "Indian Forest Trees" fulfilled ordinary requirements, to which Troup's "Sylviculture of Indian Trees" and Stamp's "Vegetation of Burma" afforded additional information. Mr. Champion's objective was different from that of forest botany pure and simple. As he correctly states, "The need of a standard classification for the important forest types of India has long been felt in connection with sylvicultural work, particularly in its application to forest management under working plans, and this need has led to the adoption of local standard types in some provinces".

In temperate Europe the forest types are comparatively few in number, and for the purposes of the working plans officer easy to define without danger of misapprehension. In the tropical and sub-tropical forest regions, the position is far more complicated. This problem had come up previously at sylvicultural conference meetings held at Dehra Dun; one of the puzzling undefined types, for example, being the term 'tropical evergreen'. Mr. Champion solicited the assistance of the provincial research sylviculturists, and as a result a certain amount of a variable material was sent in. This, with such information as had been already published, was utilized in conjunction with his own recorded observations made in all parts of India during the preceding twenty years in the compilation of the publication under review.

As the author says, working plans generally include a description of forest types with which they are concerned, and give lists of the characteristic plants of each. In the present reviewer's opinion, working plans should always include a description of the forest types, etc. But it is essential that the forest officer carrying out the provisions of the plan should know exactly the forest type or types to which the working plans officer is alluding. Herein lies the value of Mr. Champion's work. It is by no means

to be regarded as complete. "The account of the Peninsular and Burma sub-tropical forest types is outstandingly incomplete", he tells us; and there are other parts in the monograph where further information is required, and the author adds that criticism of the classification adopted will be welcomed. The work is illustrated by some typical photographs, for the most part taken by past and present forest officers, also by an informative coloured diagrammatic map showing the distribution of climatic types.

The monograph comprises some 286 pages and may be regarded as a valuable aid to the forest officer engaged upon important work in forest management and working plans. A brief résumé only can be attempted here.

A classification of the forest types in India is attempted, based on four climatic zones from the point of view of temperature—tropical, subtropical, temperate and alpine. Each zone is subdivided on available moisture as reflected by the relative importance of evergreen, deciduous and thorny trees. Whilst the form of the tropical forests is similar on both sides of the Tropic of Cancer, the author considers that the flora is sufficiently different to render subdivision into northern (quasi-subtropical) and southern variations advisable. Omitting moist and dry alpine scrub, thirteen formations are distinguished, seven of them subdivided into northern and southern variations.

The six tropical formations are sub-divided into thirty-three forest types, most of which are admittedly composed of several associations, these being indicated where possible; important edaphic variants (twenty-four) are listed and successions are discussed leading to the recognition of twelve primary and ten secondary important seral types. Subtropical and temperate forests are dealt with in a similar fashion. For each type a general description of the forest and the locality factors is given, with plant lists for typical examples, and ecological notes.

The author stresses the lacunae to be filled up; but in even its present form his monograph should be of considerable use, not only to India but in the forests of the world where similar problems are being faced.

Science News a Century Ago

The Royal Society

At a meeting of the Royal Society on March 7, 1839, William Hopkins read the third part of his paper "On the phenomena of Precession and Nutation, assuming the Interior of the Earth to be a Heterogeneous Fluid". The objects of researches of this kind, said the author, were not merely to determine the actual state of the globe, but also to trace its past history through the succession of ages, in which the matter composing it has probably passed gradually through all its stages between a simple elementary state to that in which it has become adapted for the habitation of man. In this point of view the problem was not without value, as demonstrating an important fact in the history of the earth, presuming its solidification to have begun at the surface—namely, the permanence of the inclination of its axis of rotation, from the epoch of the first formation of an exterior crust. This permanence had frequently been insisted on, and was highly important as connected with the author's speculations on the causes of that change of temperature which had probably taken place in the higher latitudes.

A Royal Institution Conversation

On March 8, 1839, a conversazione was held at the Royal Institution. In its report of the meeting the *Mechanics' Magazine* said: "Mr. Read exhibited what we think to be a very important application of his patent instrument, commonly called the 'stomach pump', namely to the restoration of suspended animation. Besides extracting noxious gases in other cases, and the naturally vitiated state of the air in the lungs of drowned persons, the apparatus is competent to keep up an artificial breathing, the supply of air being both warm and pure, and rendered more exciting if thought proper, by a mixture of oxygen with it. . . . The Royal Humane Society will assuredly hasten to add this to their other means of recovery. We would advise Mr. Read to furnish with the apparatus, air tight bags, which being supplied to the extremities, and the air exhausted by the same instrument, would tend to relieve congestion of blood in the head and other parts, and facilitate its circulation."

Niepce, Daguerre and Talbot

In its column of weekly gossip, the *Athenaeum* of March 9, 1839, said: "During the discussions which took place in Paris respecting the priority of the discovery of M. Daguerre and Mr. Talbot, the name of M. Niepce was incidentally mentioned as the person to whom the former was indebted for the first idea of fixing the images represented in a camera obscura. Subsequently M. Niepce's claim to honour has been more fully admitted; and this has been singularly confirmed by Mr. Bauer, in a letter published in the *Literary Gazette*. Mr. Bauer therein states that, in 1827, he became acquainted with M. Niepce, then on a visit to his brother at Kew; that M. Niepce made known to him, and others, that he had discovered a means of 'fixing permanently, the image of any object by the spontaneous action of light', and exhibited several specimens. That by the advice of Mr. Bauer, he, M. Niepce, drew up a memoir on the subject, dated 8th December, 1827, which he forwarded to the Royal Society, but which was subsequently returned, because it is contrary to

the rules of the Society, to read a paper referring to a process which is not disclosed. . . . Thus, then, the question of priority, as between England and France, is settled beyond all dispute: at the same time we must observe that the processes of M. Daguerre and Mr. Talbot are manifestly different."

Specimens of Niepce's work belonging to Mr. Bauer and to Mr. Cussels were submitted to the writer of this notice, who said that they were all on pewter, apparently covered with a very thin coating of transparent varnish, "but whether this varnish was applied before receiving the impressions, or subsequently, to fix them, is not obvious; we incline to the latter opinion".

University Events

CAMBRIDGE.—The Rockefeller Foundation has allocated £650 as a grant to the Cavendish Laboratory for the purchase of instruments and for assistance in connexion with researches carried out by the Cavendish Professor on the application of X-ray technique to the study of crystals of biological importance.

F. J. Scrase, of Trinity Hall, has been approved for the degree of doctor of science.

At Trinity College, Dr. A. L. Bowley, emeritus professor of statistics in the University of London, and Sir Henry Dale, director of the National Institute for Medical Research, have been elected honorary fellows.

Dr. L. Wittgenstein, formerly fellow of Trinity College, has been appointed to succeed Prof. G. E. Moore, professor of philosophy, who will retire at the end of the current academic year.

LEEDS.—The following appointments have recently been made: W. G. France, demonstrator in anatomy; Eustace A. Horne, demonstrator in pathology and bacteriology; H. S. Shucksmith, surgical tutor; Donald A. McKenzie, lecturer in agricultural bacteriology.

LONDON.—Dr. P. H. Himsforth has been appointed, as from April 1, 1939, to the University chair of medicine tenable at University College Hospital Medical School. Since 1936, he has been deputy director of the Medical Unit at University College Hospital.

The title of professor of physics in the University has been conferred on Mr. Gilbert Stead, in respect of the post held by him at Guy's Hospital Medical School, and the title of reader in physics in the University on Mr. O. T. Archer, in respect of the post held by him at the Imperial College of Science and Technology.

The following doctorates have recently been conferred: D.Sc. on Miss Irma I. Andersson-Kottö, of the John Innes Horticultural Institution; F. M. Haines, of Queen Mary College; William Pugh, of King's College; Isaac Schapera, of the London School of Economics; R. B. Cattell and S. H. Straw.

OXFORD.—In Congregation on February 27, the honorary degree of D.Sc. was conferred on Don Pio del Rio Hortega, director of the National Institute of Cancer and of the Laboratory of Normal and Pathological Histology in Madrid.

Societies and Academies

Paris

Academy of Sciences (C.R., 208, 313-396,
Jan. 30, 1939).

A. CHEVALIER: Future of cotton in the [French] possessions and organization of scientific researches on this crop.

P. LÉVY: A problem of M. Marcinkiewicz.

C. EHRENMANN: The variety of plane generators of a real quadric and the topology of an orthogonal group with n variables.

L. DIEHOUSSE: A differential equation for which the point $x = y = 0$ is a focus.

H. PAILLOUX: The movement of a thread on which a small ring slides.

G. SARTORY: Formation of thermal convection ascending currents above a region uniformly heated by radiation.

J. VIGNAL: Character of errors affecting levellings.

G. BECK: A theorem on the structure of the proton and of the neutron.

M. PABODI: A phenomenon of wave propagation in a line of magnets.

L. and E. BLOCH: Extension of the spectrum of tellurium into the extreme ultra-violet.

G. UNGAR: Theory of photo-dichroism.

M. E. NAHMIAS: Probable emission of mesons in certain nuclear disruptions.

F. JOLIOT: Experimental proof of the explosive disruption of the nuclei of uranium and thorium under the action of neutrons. The radio-elements formed in uranium and thorium, identified by chemistry as barium or rare earths, are due to nuclear disruption with large release of energy.

Mme. I. CURIE and P. SAVITCH: Radio-elements formed in uranium and thorium irradiated with neutrons. At least three radio-elements similar to the rare earths are produced, and also an alkali body of period 18 min.

A. PORTVIN, P. BASTIEN and L. GUILLET, JUN.: Nature and stability of some special cementites.

Mlle. M.-L. JOSSEN: Formation of bromous acid by the action of bromine on silver nitrate.

P. DUMANOIS, G. REICHENAUER and M. PRETTER: Combustion of mixtures of hydrocarbons: mixtures of decahydronaphthalene and tetrahydronaphthalene.

A. KIRGMANN: The ethylenic frequency in vinylic esters.

Mlle. B. TCHOUBAR: Action of magnesium bromide etherate on dimethyl-1.4 epoxy-1.2 cyclohexane.

A. LEHMAN: Estimation of phenolic and naphtholic hydroxyl by means of benzoic anhydride.

R. PAUL and G. HILLY: Application of Raney nickel to the hydrogenation of some acids with the furanic nucleus.

A. BOUILLIER: Reversible transformation in the copper-aluminium alloys containing between 7 parts and 16 parts in a hundred of aluminium.

F. D. LA TOUR: Dilatation and polymorphism in the fatty acids.

R. SOYER: The fallen cliff at Ivry-sur-Seine (Seine).

M. LAFÈVRE and P. BOURELLE: Stability of ornamentation in species of the genus *Pedicularis* Meyen.

L. EMBREGER: Structure of the flower of the Polygonaceae.

H. HUMBERT: An aberrant type of *Casalpinia* of Madagascar.

R. HENRI: Existence of a group of *Boletus* [fungi] with free tubes.

A. DE OUGNAC and H. BELVAL: Nature of the glucide of a hybrid [between two genera of Gramineae] differing in their glucidic reserves.

R. DUGHI: Domain of stability of lichen symbiosis: emantioxy [resistance to drought].

P. DE BERRIDO-CARNERO: Curarization and chronaxy.

L. LAPICQUE: Observations on the preceding note.

F. RATHERBY, M. DIBOT and P.-M. de TRAVERSE: Consecutive hypoglycemia with digestive absorption of insulin. Effects were obtained, but not proportional to the quantity of insulin used, by limiting the action of proteolytic ferments with an antidiastase.

Mlle. M. HAMON: Chemical constituents of the envelopes of cephalopod spermatophores.

L. LESOUBE: Variations of the formol and phthalein acidities in the urine: interpretation by the graphic method.

L. LUTZ: Soluble ferments secreted by hymenomyces fungi: conjugated antioxygen action.

A.-R. PRÉVOT: Increase of the toxigenous power of a stock of *Plectridium tetani* by passage in acid brain broth at moderate temperature.

Budapest

Hungarian Academy of Science, January 23.

J. BARTA: Uniformly stretched and optionally loaded plates.

J. BARNÓTHY and M. FORRÓ: Influence of meteorological factors upon the intensity of cosmic ray showers. From the material measured during a year, the barometric, temperature and magnetic effects are determined as well as the phase and amplitude of the daily and sidereal wave. The differences between these values and those obtained with a corresponding vertical arrangement can even be quantitatively explained with the help of the meson disintegration hypothesis.

Prague

Czech Academy of Sciences and Arts, January 21, 1938.

K. HRUBÝ: Development of the embryo-sac in *Erythronium dens canis* F.

March 11.

J. MILBAUER: Prolonged action of concentrated sulphuric acid on acetylene in the cold. The solutions turn yellow to dark. This change is catalysed positively by HgSO_4 , SeO_3 , CuSO_4 , V_2O_5 , Ag_2SO_4 , MoO_3 ; practically inert are As_2O_3 , SiO_2 ; negative catalysts are Sb_2O_3 , PbSO_4 , HCl , ZnSO_4 , SO_2 , K_2SO_4 , $(\text{NH}_4)_2\text{SO}_4$.

J. PETEREK: Historical evolution of the bay at Neeber.

A. VELICH: Effect of essential oils on the germinating grain and bacterial growth.

May 20.

J. MILBAUER: New behaviour of mannitol as a negative catalyst. It retards the oxidation of hydrogen or ferrous sulphate by hot sulphuric acid, but not that of carbon monoxide.

V. TRKAL: A fundamental equation of the electron theory.

ZD. KÖCHER: Experimental studies of the resorption of K-strophantidin and convallamarin.

ZD. KÖCHER: A contribution to the study of the accumulative effect of some cardiacs.

R. RÖHLKA: A contribution to the recognition of Barrandian trilobites. (2).

K. KOUSKÝ: Some modifications of given topology.

ZD. ROTH: Geological conditions around Lučivná below High Tatra.

October 21.

J. MILBAUER: Dissociation of urea nitrate in aqueous solution.

J. MILBAUER: Application of Bunsen's photometer in enlargements.

J. MILBAUER and ZD. MILBAUER: The investigation of some relationships in the action of acetylene on sulphuric acid, at room temperature. The factors influencing this reaction. Concentration of sulphuric acid, of the positive catalyst, HgSO_4 , and of the negative catalyst $(\text{NH}_4)_2\text{SO}_4$ are expressed by empirical mathematical formulae.

J. MLÁKOVSKÝ: Registration of the reaction of frog's iris to light.

J. PETRBOK: Stratigraphic chronology of non-marine layers of the Black Sea quaternary in Bulgaria.

K. KAVINA: Antholysis in *Cerastium Cespitosum*.

P. ČERH: The electromagnetic field of a dipole between two parallel planes.

Forthcoming Events

[Meetings marked with an asterisk are open to the public.]

Monday, March 6

UNIVERSITY OF LONDON, at 5.15.—Prof. E. D. Adrian, F.R.S.: "Manifestations of Activity in the Nervous System".*

UNIVERSITY COLLEGE, LONDON, at 6.—Prof. A. Frey-Wyssling: "The Submicroscopic Morphology of Protoplasm and its Derivatives (succeeding lectures on March 7 and 9)."

Tuesday, March 7

WILLOWAY RESEARCH INSTITUTION, at 5.30.—Prof. W. Schlemmer: "Chemotherapy" (succeeding lectures on March 8 and 9).*

Friday, March 10

ROYAL INSTITUTION, at 9.—Dr. W. H. Hatfield, F.R.S.: "New Researches in Steel Metallurgy".

INSTITUTE OF METALS, March 8-9.—Annual General Meeting at the Institution of Mechanical Engineers.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

TEACHER OF SCIENCE OR ENGINEERING in the Luton Technical College—The Director of Education, Shire Hall, Bedford (March 6).

PROFESSOR OF PHYSICS AND ELECTRICAL ENGINEERING in the Royal Naval College, Greenwich—The Director, Education Department, Admiralty, London, S.W.1 (March 16).

LECTURER IN PHYSICS in the University of Sydney—The Registrar (May 1).

ASSISTANT in the Intelligence Section of the Mineral Resources Department of the Imperial Institute—The Establishment Officer.

The Unity of Knowledge

IN his anniversary address to the Royal Society, Sir William Bragg has treated a subject which, as he said, seems to exhibit a greater importance the more closely it is examined. The very great increase in the output of the records of research has placed scientific societies in a difficult position. There is correspondingly more to be published and, at the same time, publication costs have increased. The long rows of periodicals on the shelves continue to grow, the annual volumes increase in size and divide into two or four. Still the papers come pouring in, and even the rate of flow increases. It is a healthy growth, which we do not wish to check; but the practical difficulties need to be solved.

The principal reason for the publication of the results of research is that they may be of service to mankind. The preparation and presentation of these records so that they may be sufficiently appreciated and can be incorporated with understanding into every activity, scientific, intellectual and physical, to which they may apply; is one of the essential duties of a society. In Sir William Bragg's own words, "We are, at least, bound to see that our acquired knowledge is rightly stated so that it can be rightly used." Because the results of research have become so voluminous and so important, the manner of stating them, of arranging them and of storing them, has also become important.

The proper appreciation and application of new discoveries is being hindered at present by increasing specialization, employing a terminology and a mathematical apparatus which are intelligible only to a few specialists in some one subject. Anyone who has completed a piece of research may think it necessary to set out his facts in detail for the use of the expert who is working in the same

subject, and is familiar with the technical terms and the hidden difficulties. Yet such writings make dull and difficult reading for the great majority of those who are interested in scientific discovery. The number of those who can study critically a paper of a certain type is distressingly few. The difficulty even of finding referees capable of judging its merits is known only too well. The paucity of attendance and the lack of good discussion, when such papers are read, is so disappointing that an increasing number of papers are taken as read.

The publication in advance, in the *Proceedings of the Royal Society*, of summaries of papers received has been appreciated, as providing both an earlier announcement of discovery, as well as giving a general idea of the trend of research to those who are not specialists. Such summaries are the expression of a natural reaction to the increasing difficulties due to growing specialization, which tends to take discoverers out of sight of each other and of the main body of scientific workers. Summaries indicate the recognition of a principle, which demands acceptance, namely, that discovery must be accompanied by exposition.

The summaries required are more than mere digests of papers. They differ from the papers themselves in being addressed to a wider circle of readers, a circle that may include the experts, but which contains also many others, who should, in fact, receive the principal attention. Such a summary may be more difficult to write than the paper, because it must take into account the interests and modes of thought of those who may be unable to read the paper itself, but will gladly absorb its meaning, especially if there is a connexion with their own work. When the summary is written with this wider view it becomes literature,

though the paper itself may be no more than a record. The only way to facilitate the growth of a sound general opinion is to insist that a general account shall be given that is intelligible to a sufficient number.

Now, if the scientific worker is required, not merely to observe and to record, but also to share his knowledge with the world, he needs certain qualifications and a certain education, which are less necessary in the more restricted field. He is dealing not merely with facts, but also with men: his work enters the humanities. As Sir William Bragg points out, this is really a great matter. Its importance arises from the tremendous consequences, which are now obvious, of the increase of knowledge of Nature. To charge scientific men with the responsibility for the evil uses sometimes made of their discoveries is absurd. But this responsibility is theirs, that they shall explain what they find so that it may be properly understood; and none but themselves can rightly describe it.

This problem, urgent as it is, cannot be fully solved while school and college still maintain an artificial division between two forms of teaching, respectively described as 'science' and the 'humanities'. If Plato was right in defining science as knowledge of what eternally exists and not what comes for a moment into existence and then perishes, science and the humanities are one. The "Principia" is an item of literature, as the discovery of radium is an event in history. The artificial separation of science from the humanities in education tends to the division of the adult into two distinct classes, whose minds are complementary, the one to the other, but each essentially incomplete and incapable of comprehending truth as a whole. Mutual distrust may result in after-life. The seeds of social strife are sown at school. May not present international disputes be traced in large measure to defects in national systems of education? The existence of this evil is too evident to need examination. Steps must be taken to eradicate it now. The basis of education must be broadened. The humanist must learn to understand the inner working of the common things of life. As Pope would teach him:

"Go, from the creatures thy instruction take.
Learn from the birds what food the thickets yield;
Learn from the beasts the physics of the field;
The art of building from the bee receive;
Learn of the mole to plough, the worm to weave;
Learn of the little nautilus to sail,
Spread the thin oar, and catch the driving gale."

Likewise the man of science should learn from the same poet that:

"True expression, like th' unchanging sun,
Clears and improves whate'er it shines upon;
It gilds all objects, but it alters none."

Specialization there must be, of course—a divergence in study at later stages. But men of different types of mind must be kept together more than at present, so that, when they meet in the affairs of the world, they can understand each other. Practical difficulties can be surmounted, now that the need is clear. The sharp distinction must disappear. Education must be founded on the unity of knowledge.

Already the humanities and science have joined hands in the service of mankind. Scientific societies can contribute towards the needed reform by insisting on the publication of adequate summaries of original contributions to knowledge. When a new departure in experiment or theory is made, or a new fact is discovered, a careful and complete explanation must be made. If the novelty leads, as often, to a steady output of observation, extension, confirmation and illustration, there must come a time when complete publication to the world becomes unnecessary and even tiresome. Summaries, properly written, of such continuation material should be enough. For the benefit of the comparatively few experts who need them, photographic reproduction of the complete material could be made at a fraction of the cost of printing. The proceedings of societies would thus become more handy, interesting and useful, and their cost would be reduced.

The so-called micro-film, the use of which is discussed in an article on pp. 393-395, offers one means for the photographic reproduction of bulky reports. Complete copies of lengthy documents can be prepared on cinematograph film at the cost of a penny or so a page, and these can be read, in libraries or the private home, by means of optical projectors that enlarge the pictures to full size. The method has now well passed the experimental stage. Already it is being used extensively for the reproduction of articles in periodicals, rare and out-of-print books, manuscripts and documents of all kinds. The United States has taken the lead in the exploitation of the new process. The time is ripe for the creation in Great Britain of a centre, where micro-films and other photographic reproductions of material for the use of scholars can be produced with economy and efficiency.

Documentary Photography and Research

By Dr. S. C. Bradford

RECOGNITION of the document, manuscript or printed, as an instrument of research, demands intensive study of the processes of collecting, classifying and distributing documents. Prominent among the subjects considered during the past twenty years, in the circles concerned with this endeavour, has been the photographic reproduction of documents, and especially the application of the micro-film to this end.

The value of the method is now recognized alike by historians and scientific men. Recently its importance was emphasized by Sir William Bragg in his anniversary address to the Royal Society. Photography has become the most suitable means of reproducing books and manuscripts, of which a comparatively small number of copies is required. It may be employed to serve the needs of a particular student, or, as a means of publication, alternative to the issue of a printed text. It is suitable as a method for the preservation of material, whether in print or manuscript, which is perishable in nature, or of considerable bulk in its original form.

Of the various photographic processes available for the reproduction of documents, collotype and photolithography have already taken their place as everyday operations of printing. It is time to consider how best to make use of the facilities offered by photography for the production of a smaller number of copies of documents. This is a matter of considerable moment, in which the scientific public is intimately concerned. It is important that the public should be cognizant of the relevant facts, which shall be stated succinctly.

The photostat and its various modifications are too well known to need description. Two other processes are specially notable, namely, reflection copying and microphotography. Perhaps the former is of greater theoretical interest. In this method, sensitized paper is pressed into contact with the material to be copied, so that light may pass through the photosensitive layer to the surface of the document, whence it is reflected back again through the sensitive layer. The difference in the amount of light reflected from the dark and light portions of the document is utilized to form the photographic image, which is produced in continuous tones, though with rather greater contrast. Silver bromide paper may be used in the process, giving a full-size reversed negative image, from which positive 'prints' must be made. Such are the Ruthurstat and Rectophot processes.

Perhaps the most intriguing, and at the same time most valuable, method is the so-called Retocooe process, of recent introduction, and using thin sheets of 'Cellophane' coated on one side with a diazo compound. After exposure to an arc light, mechanized treatment with a suitable solution immediately develops a full-size positive image by the formation of a dye-stuff. The picture becomes dry instantaneously and is made ready for delivery by pressing the tissue on to a sheet of tacky white paper to show up the image. The complete operation occupies three minutes. Should a number of copies be required, they can be printed at the rate of perhaps three or more a minute, in black on white paper, from a brown-toned transparency, at a cost of a farthing a piece, for octavo size. Neither lens nor shutter is needed in the apparatus, which can be operated by any member of the staff in full daylight. At present, the cost of the materials for making a single positive copy by this method is very slightly more than that for a negative copy by the photostat method, or scarcely more than half the cost for a positive copy; the difference being negligible in comparison with the labour and overhead charges involved, which may amount to half a crown for each order of an average of four pages. The apparatus itself, of course, is much cheaper, while the cost of producing a number of copies is remarkably low. Now that typewriters are available with a double shift, giving three characters to a key and a range ample for typing scientific papers, this method is very suitable for the reproduction of such papers, of too limited an interest to justify printing.

The microphotographic process, which, on account of its cheapness, the small bulk of the copy, and the need for the production of grainless films and the design of new types of apparatus, has stimulated so much interest in documentary photography, was first described in 1907 by an eminent Belgian, Prof. Robert B. Goldsmidt, and M. Paul Otlet, who is well known as one of the founders of the International Federation for Documentation. Their invention was published in the Belgian *Journal des Brevets*, in an article entitled "Une forme nouvelle du livre—Le livre micro-photographique". The process consisted in the microphotographical reproduction of documents on standard cinematograph film and their enlargement for reading by the projection of an optical image. The term 'photoscope', given originally by Prof. Goldsmidt to his reading apparatus, can scarcely be improved. Complete mechanization of the method has

enabled exposures in a continuous run to be made at the rate of three or four hundred an hour, with a corresponding speed of processing the film and a resulting cost for material of about a halfpenny per exposure. The design of a perfect photoscope has presented the greatest difficulty, and although tolerably efficient instruments are now on the market, room for improvement still remains. As an alternative method, the micro-negative may be enlarged into a full-size positive photograph. But this method, involving two exposures, cannot compete in cost with methods that produce positive copies directly. Necessarily the same overhead charges apply, as with other methods. These completely swamp the cost of materials, when only a few pages are ordered, so that the cheapness of the process is fully realized only when applied to the reproduction of a large number of pages at a time.

Thus, as was foreseen by its inventors, the great value of this method lies in its application (1) to the reproduction of bulky material, such as complete manuscripts, rare books and newspapers, and (2) as a potential means for the publication of records, reports and other documents of too limited an interest to bear the cost of printing.

The microphotographic method is suitable for the reproduction of works of considerable length, whether in a few or a comparatively large number of copies. By its means, masses of historical material could be made available or more readily accessible to the student. The method can be used to supply individual students with copies of otherwise unprocurable books, or to relieve the librarian of anxiety caused by the too frequent handling of rare originals. It may have greater value as a means of reproducing large works of reference, such as the Statutes of the Realm, or of assembling complete texts from widely scattered originals. The process makes possible the study, in the reader's own home, of the foreign press, in a manner which can be achieved at present only by prolonged visits abroad. Film photographs can be used for the preservation of records otherwise likely to be destroyed. Microphotography of newspapers facilitates the collection of complete files of the rarer journals at small cost and provides a method of preservation of such as are liable to disintegration. It relieves libraries of costs for storage and binding. Thus a bound file of the *New York Times* requiring 59 cubic feet of storage space, occupies, in film form, only $1\frac{1}{4}$ cubic feet. The method offers also means of avoiding inter-library loans of rare books.

In adopting photographic methods as a means of publication, the editions produced fall naturally within the scope and protection of the copyright laws. Arrangements must, therefore, be made to

satisfy the holders of any copyright in the originals reproduced, as would be done for works published in any other way. No difficulty arises from this fact. But, it is important to discriminate between the use of photography for the publication of a considerable edition of a work, and its utilization as a convenient means of copying an extract from a volume for the purpose of private study, or research. In the past, photographic copies of more or less inaccessible scientific papers have been of much service to research workers, on occasion. This facility should not be limited.

Fears have been expressed that the unrestricted sale of micro-photographs of articles in periodicals might 'kill' the journals. Let us be clear upon this point. In library experience, rarely is a second request received for a photograph of the same article. After the passing of the period when a discovery is first made known, by the publication of an article in a scientific magazine, references to that article are usually confined to single consultations, made by one, or occasionally a few, experts working on a cognate subject, or subjects. Such experts need to refer, not merely to one article, but to a number of articles, published at different times and in different periodicals. For the rapid performance of the bibliographical survey, which must usually precede the commencement of a new laboratory investigation, it is essential that comprehensive libraries should be available, where the experimentalist may find ready to hand the original literature bearing on his work. It is not an assistance, but a hindrance, to have to wait while photographic copies are being made of articles urgently needed for consultation. This applies, whether only one example of the original document exists, or whether a number of copies have been made and deposited in other libraries.

Photographic reproduction will be of service as a new means of publication; copies of periodicals so published will be deposited in libraries; but photography will not take the place of libraries, or kill the journals. Only when a library does not contain a copy of a paper needed by a research worker, is he glad to avail himself of the possibility of obtaining a photograph from another library. He would soon complain, if his library should cease to take periodicals, in the hope of satisfying him with photographs obtained from other sources.

A single photographic copy of an extract, whether of microscopic or legible size, becomes useful when the work itself is not available for consultation. The supply of such copies is not publication, in the sense of making available to the general public. It has not restricted the continual growth in number of new periodicals, nor does it appear to have diminished their circulation. Publishers have

not objected to the practice, and authors are concerned rather to make their discoveries better known. The making of a single copy of an article, by any means, is not a trespass upon the moral rights of the holder of any copyright. Carried to the extreme, such an idea must prevent the loan of books, or even the establishment of libraries for general use. It would be an ill service to science, if the advent of microphotography should be the cause of the suppression of a useful aid to research.

In order to take full advantage of the facilities offered to research workers by the various methods of documentary photography, the organization of the service would require to be placed in the hands of a central institute, which would be in a position to study the many problems involved, to choose the best means of tackling individual cases and to

bring about the standardization of apparatus and material. The present tendency to leave the making of photographs of documents to individuals, commercial firms, and miscellaneous institutions, working independently, is both wasteful and a source of confusion. Expensive apparatus is used intermittently, overhead charges are increased and experience wasted. Moreover, the lack of agreement upon standard measurements creates the possibility that microphotographs made by one agency may prove to be unreadable upon apparatus available in another place. Already the United States has led the way by the foundation of the American Institute of Documentation. A similar centre is needed in Great Britain, where production may be organized and the fullest efficiency and minimum cost achieved.

Josiah Wedgwood and his Portraits of 18th Century Men of Science*

By Dr. John Thomas

THE eighteenth century gave birth to some remarkably interesting personalities in the realms of both industry and science. From the Midland manufacturers in the persons of Wedgwood, Boulton and Watt, there can be singled a trio who became fellows of the Royal Society. In science, the Midland men of fame include Joseph Priestley and Erasmus Darwin. The spirit of inquiry of the age, with its zest for experiment, led Wedgwood to convert his manufactory into an industrial "elaboratory", as he termed it. He was determined to convert crude clays into artistic ceramic products. He had to wrestle with all the four familiar elements of philosophers in the pre-scientific age—fire, air, earth and water. His "Trial Books" now in the Etruria Museum justify his claim to be considered a man of science.

Josiah Wedgwood was elected a fellow of the Royal Society in 1783, and made several contributions to the *Philosophical Transactions* in 1782, 1784 and 1786. His pyrometer, which was the subject of his Royal Society papers, was the result of experiments extending over a period of six years. It is a very simple instrument marked and graded to indicate the shrinkage of clay bodies when inserted in the potter's oven. At first, Wedgwood placed small cylinders of clay at the wide tapering end, but later he made cylindrical balls or marbles of clay, which he called pyrometrical

pieces. These "contraction bits" have been used regularly in potteries the world over since the invention of the pyrometer by Wedgwood.

This thoroughness in scientific exactness was not confined to the firing of the ware, but it permeated the earlier stages of preparing the clay. The potter's mill, like "the mills of God", is expected to "grind exceeding small"; hence Wedgwood's anxiety to replace the wind- or water-mill with the more reliable source of power found later in Watt's steam engine. The Boulton and Watt archives* contain ample evidence of Wedgwood's faith in the new scientific inventions of James Watt. At Etruria, the last steam engine installed by Watt in 1800 worked continually until dismantled in 1912. We thus see a powerful link between Etruria and Soho.

There were earlier links between Wedgwood and Boulton when Fothergill was his partner. In the earlier days of his pottery career, Wedgwood sent small cameos and pottery trinkets to Soho to be mounted in metal before being sold by jewellers. Arising out of this kind of trade, where pottery was a subsidiary of the metal trades, we get a further commercial link, where Boulton and Fothergill often acted as wholesale merchants for Josiah Wedgwood until he later set up his own sales room in London. Like the Prince of Potters,

* From a Friday evening discourse at the Royal Institution delivered on December 16. A small selection only of the many medallions by Wedgwood mentioned during the discourse are reproduced here.

* The Soho order book for steam engines sold to Staffordshire shows orders from Etruria in 1782, 1784, 1793 and 1800. In 1793 Wedgwood drafted a document for Boulton and Watt stating the performance he expected of the steam engine in his pottery.

these two Soho manufacturers, Matthew Boulton and his later partner James Watt, were elected fellows of the Royal Society, in 1785. But as the versatile Watt was in his way more or less a skilled artist and sculptor, another link was forged between Watt and Wedgwood. When the former retired from the Soho factory, he carried on his experiments in his garret at Heathfield. Here he invented his now famous mechanical sculpturing machine for producing enlarged or reduced cameos or busts, "made," as Watt wrote to his friends, "by a young artist just entering on his eighty-third year." The moulds and pottery models for this work were supplied to Watt by his bosom friend, Wedgwood.

Sir Humphry Davy, in a discourse introductory to a course of lectures on chemistry at the Royal Institution in 1802, remarked that the knowledge of chemistry has improved the art of pottery, but he rightly emphasized also that the pottery industry has provided much of the apparatus used in scientific research. Many of these pottery implements Wedgwood supplied freely to his friend, Dr. Joseph Priestley, and even after his death his sons, Josiah and Thomas, provided Davy with porcelain and other apparatus for chemical experiments and demonstrations at the Royal Institution. In fact, Josiah Wedgwood II, when this Institution was founded in 1799, became one of the first proprietors by subscribing one hundred guineas to its funds.

WEDGWOOD PORTRAYS MEN OF THE 18TH CENTURY

With his love of science and association with scientific men, it is not surprising that Wedgwood devoted his energies to portraying the features of some of his famous scientific contemporaries by means of his "jasper" ware. This triumph he was enabled to achieve through the medium of his new and perfect pottery "bodies". The soul of

Wedgwood ware lay to a large extent in its "body". One body, used for black busts, he called "basalt-tes". Later he discovered a body called "jasper", generally blue, green or lilac, which he used for the base or background of his portrait medallions, using white jasper for the raised faces or heads and shoulders. This body, while plastic and unfired, is pressed into a mould, which has been cast or made in plaster of Paris, usually from a design by some artist.

SOME WEDGWOOD MEDALLIONS.

Photo.: E. Harrison and Son.

THE MAKERS OF THE MEDALLIONS

The three partners associated in the production of most of the medallions [a large collection was on view in the library of the Royal Institution] were Josiah Wedgwood, Thomas Bentley, his first partner at Etruria, and after the latter's death, Wedgwood's nephew Thomas Byerley.

Bentley was a cultured Liverpool gentleman who, while in the North, was one of the founders of the famous Warrington Academy, which was the training ground of so many fellows of the Royal Society, for example, Joseph Priestley, Thomas

Pennant, and others. When Bentley removed to Chelsea his artistic temperament delighted in the company of a neighbour, Sir Joseph Banks. Bentley was a regular subscriber to the Royal Society of Arts, and he it was who spotted young Flaxman, at the age of twelve years, as a premium winner, and recommended him to the notice of Wedgwood. Until his death in 1795, Wedgwood made his nephew Byerley his partner, after giving him a good training in his own business methods at Etruria. In addition, Wedgwood had his two sons, Josiah and Thomas, as active partners from 1793. For some strange but presumably good reason, Wedgwood never made a medallion of any of his children. He was content to leave them to the skill of the artist George Stubbs, R.A., in his well-known painting of the Wedgwood family.

There was a host of artists engaged by Wedgwood for the designing and modelling of many of his medallions. From the artistic point of view the best was undoubtedly the master sculptor Flaxman.

LEARNED SOCIETIES IN THE PROVINCES: THE STAFFORDSHIRE LUNAR SOCIETY

Long before Wedgwood became a fellow of the Royal Society, he had been introduced to the circle of Midland men of science or philosophers calling themselves the "Lunar Society". It was an informal club or association of scientific men formed about 1766 by Erasmus Darwin and Matthew Boulton. The "Lunar Society" was later joined by new and brilliant recruits, like Joseph Priestley and James Watt. The members met at each other's houses every Monday nearest to the full moon, "in order to have the benefit of its light in returning home," stated Priestley. Hence its name, "Lunar Society". The members were accustomed to dine at 2 o'clock, and parted company at 8 p.m., after exchanging views on scientific topics. Wedgwood made two excellent medallions of Darwin and Priestley.

Members of the Lunar Society were allowed to introduce friends, and thus many distinguished guests were present at these philosophical and scientific banquets. Among these were fellows of the Royal Society from London and sometimes from abroad. Wedgwood made medallions

of several of them, including Sir Joseph Banks, Dr. Solander, Sir William Herschel, and Dr. Peter Camper. Some writers place Wedgwood among the visitors to the Society, but judging from his correspondence, I would be inclined to rate him as a member.

The Lunar Society in the Midlands was only one of many provincial learned societies. Spalding's Gentlemen's Society, of which Sir Isaac Newton was a member, goes back as far as 1710. In Liverpool, Bentley, Roscoe and Currie formed a scientific group. At Warrington, Dr. Aikin and, later, Dr. Priestley, before he removed to Birmingham, had been the scientific centre of another active coterie. Later, at Bristol, we had Dr.

Beddoes, with his young assistant, Humphry Davy, the centre of a scientific circle. At Norwich a scientific group centred round the Taylors and the Martineaus.

Wedgwood made medallions of several presidents of the Royal Society, and there are in existence two by him of Sir Christopher Wren and Dr. Martin Folkes. Of the Royal Society medallists portrayed by him, I will comment upon two only, although all are worthy of passing note.

Dr. Joseph Priestley was awarded the Copley medal in 1772 for his experiments and paper on soda water. Then, when Priestley resigned his post with Lord Shelburne to reside in Birmingham, Wedgwood generously afforded him

WEDGWOOD BLACK BASALTES BUST OF NEWTON.

an annual allowance of 25 guineas, a sum continued after Josiah Wedgwood's death by his son until Priestley died. In addition, Wedgwood readily came forward with generous gifts of money and goods to Priestley when the rioters burnt down his laboratory and house in Birmingham. In addition to his medallions of Priestley, Wedgwood made a fine black basalt bust.

The Wedgwood medallion of Captain James Cook is a fine one, showing the courageous face of the circumnavigator. The portrait is a replica of the Cook medal by Pingo, specially struck by the Royal Society at the instigation of Sir Joseph Banks in 1779. Though Captain Cook died on his third voyage to the South Seas, he immortalized himself, and the two fellows of the Royal Society who accompanied him, Sir Joseph Banks and Dr. Solander, naming parts of the land discovered in

New South Wales after them; they also insisted on naming a river Cook's River. The name "Botany Bay" was a special tribute by Captain Cook to his scientific companions.

Naturally, Banks was lionized on his return with Cook. Wedgwood made a medallion of Banks and his wife, fine studies by Flaxman himself. It resembles the features of Banks as a young man in Reynolds' painting. There is a Wedgwood medallion of Sir Joseph Banks, as a much older man, probably based on a portrait when in his prime, as president of the Royal Society.

Banks visited the Lunar Society, while Wedgwood was a frequent caller, when in London, at 32 Soho Square, where Sir Joseph and Lady Banks kept open house for scientific inquirers. Wedgwood supplied the historic plaque, "The Offering to Flora", symbolic of his regard for Banks as a botanist and founder of the Linnean Society, for the Adam mantelpiece in its library.

Sir Joseph Banks had the services as librarian of Dr. Carl Solander, F.R.S., a pupil of Linnaeus. Solander was responsible for Banks's botanical collection, and was his boon companion on Cook's first voyage, and on Banks's voyage to Iceland. This latter trip was undertaken in 1772, when difficulties arose with the Admiralty concerning his accompanying Cook on his second voyage to the South Seas. It is interesting to note, in passing, that had Banks joined Cook on his second voyage, he would have chosen Priestley to accompany him as official astronomer. But the Board of Longitude, as the Admiralty was then called, showed no "latitude" regarding Priestley's unorthodox religious opinions.

Banks's party to Iceland visited the Western Isles of Scotland. The Isle of Staffa, with its geological interest, was discovered by Banks, and Wedgwood promptly decorated one of his famous Catherine II plates with the Isle of Staffa scene as a tribute to his friends, Banks and Solander. The latter was also engaged by the Dowager Duchesses of Portland as her librarian in charge of her rare collection of plants and rare antique vases. Among the latter was the now famous Barberini vase, which Wedgwood reproduced so perfectly in pottery.

In dismissing the many-sided connexions of Wedgwood with these three world voyages to the Antipodes, it will be interesting to study the famous Sydney Cove medallion specially executed by Wedgwood in 1789 to commemorate the founding of Sydney in 1788. It was made from clays from Sydney Cove, originally obtained through the good services of Sir Joseph Banks from Captain Phillip, first Governor of New South Wales. The subject of the medallion is "Hope addressing Peace and Plenty, Art and Labour".

The medallion inspired Dr. Erasmus Darwin to poetry in his "Botanic Garden".

Dr. Erasmus Darwin, the poetical and philosophical physician of Lichfield, was the subject of one of the finest portrait medallions in the group of Staffordshire fellows of the Royal Society. By his side is Dr. Johnson, his one-time fellow-resident of Lichfield. At one of the famous meetings of these two Staffordshire literary giants, Darwin, who stammered badly, was asked by Johnson: "Don't you find it very inconvenient stammering, Dr. Darwin?" "No, sir," replied Darwin, "because I have time to think before I speak and I don't ask impertinent questions."

Two Staffordshire peers figure among Wedgwood's portraits: Admiral Lord Anson, who circumnavigated the world in 1744, and was a neighbour of Wedgwood, as also was the Marquis of Stafford, better known as Earl Gower, and the illustrious ancestor of the present Duke of Sutherland.

Leaving these Staffordshire celebrities, we can study a few of the medical fellows of the Royal Society, who are portrayed in the medallions. Many of them were leading lights of the Royal College of Physicians. Among those of whom medallions were made by Wedgwood were John Woodward, famous as a geologist, Henry Pemberton, a physician employed by Newton to superintend the third edition of the "Principia" in 1726, and John Freind, brother of the equally famous Robert Freind, headmaster of Westminster School. The former was physician to Queen Caroline. Two other notable men were Dr. Ingenhousz and Dr. Peter Camper, both of whom were guest lecturers to the Lunar Society. Wedgwood made a fine medallion by Flaxman of Dr. John Fothergill, reputed to have had one of the finest botanical gardens in Europe. Another fine but smaller medallion is that of Richard Mead, physician to George I., Sir Isaac Newton and Sir Robert Walpole.

Two very interesting medallions depict the secretaries of the learned societies of which Wedgwood was a fellow; one is of William Stukeley, secretary of the Society of Antiquaries, the other is of Samuel Horaley, secretary of the Royal Society, who later became the Bishop of St. Asaph. It is a proof of Wedgwood's impartiality in the choice of subjects for his medallions that Horaley, who led the abusive personal attack on Sir Joseph Banks, when president of the Royal Society, is included in his collection. Not unconnected with this incident was the violent and protracted attack on another of Wedgwood's personal friends, Priestley, by the virulent pen of this politically minded prelate. He personally attacked Priestley and his views in his famous

theological work, entitled "Seventeen Letters to Dr. Priestley". In his fight with Banks, this pugnacious priest was completely routed, along with his second, Prof. Charles Hutton, who had to beat a hasty retreat in their assault on the august and dignified president of the Royal Society.

ARTISTIC AND LITERARY FELLOWS OF THE ROYAL SOCIETY

One of the foremost of these was Sir Joshua Reynolds, P.R.A., the most famous British artist of the eighteenth century, if not of all time. He was a personal friend of Banks and Wedgwood, both of whom he painted from life. The Wedgwood portrait medallion of Sir Joshua Reynolds is by Flaxman, who also modelled Reynolds' intimate friend Warren Hastings.

Another personal friend of Sir Joseph Banks was Thomas Pennant, the antiquary and naturalist, and author of the famous books "Tours in Wales" and "Tours in Scotland". He was a constant companion of Banks and Solander on their botanical excursions through Wales, a favourite haunt of Wedgwood also.

Last but not least famous in this group was Edward Gibbon, the author of "The Decline and Fall of the Roman Empire". It is from Gibbon that we have a pen picture of Sir Benjamin Thompson, later known as Count Rumford, the founder of the Royal Institution. In a letter to Lord Sheffield, dated September 17, 1783, writing before a vile crossing which he had to France from Dover, Gibbon says: "Last night the wind was so high that the vessel could not stir from the harbour. . . . What a cursed thing to live in an island! . . . The triumvirate of this memorable embarkation will consist of the Grand Gibbon, Henry Laurens . . . and *Mr. Secretary, Colonel, Admiral, Philosopher Thompson*, attended by three horses, who are not the most agreeable fellow-passengers" (*italics mine*).

I have been unable to trace any Wedgwood portrait medallion of the illustrious founder of the Royal Institution. The explanation is quite simple. Wedgwood discovered that Sir Benjamin Thompson had sat for his portrait to James Tassie, who made several paste medallion portraits of him. A magnificent Tassie medallion of Count Rumford is in the possession of the Royal Institution. Maximilian, the Elector of Bavaria, the patron of Count Rumford, is the subject of another interesting Wedgwood medallion.

My search for a medallion of Sir Humphry Davy has been a barren one. Both Count Rumford and Davy, of course, were connected with the Royal Institution long after the death of Wedgwood in 1795, although Josiah had met young

Davy in Cornwall on one of his many visits there. Through his sons Josiah and Thomas, in later years, Wedgwood had close connexion with Humphry Davy and the work of the Royal Institution.

JOSIAH WEDGWOOD PASSES THE TORCH OF SCIENCE TO HIS DESCENDANTS

Wedgwood's youngest son Tom is recognized as the father of photography. He was in his way a remarkable scientist and chemist. He had studied at the University of Edinburgh, but through chronic ill-health he had to retire from active business. After this he endeavoured to seek health and strength, through travel and association with cultured persons, among whom were counted Coleridge, Southey, Poole and Davy.

Tom Wedgwood, in an indirect way, was responsible for the training and early discovery of Humphry Davy. Count Rumford found Davy installed at the Pneumatic Institution of Dr. Beddoes at Clifton, but it was Tom Wedgwood who made a donation of £1,000 to enable Beddoes to establish his Institution and employ Davy as an assistant. When Davy was later engaged at the Royal Institution as a lecturer and professor, he became a firm friend of Tom Wedgwood. The elder Josiah Wedgwood had also contributed substantially towards the erection of the Pneumatic Institution, in which his friends Darwin, Watt and Dr. James Black had such faith, because of the enthusiasm of Beddoes. Davy recorded in the *Journal of the Royal Institution* (1, 171, 1802) some of the chemical experiments of Tom Wedgwood. The paper was entitled: "An Account of a Method of Copying Paintings upon Glass and of making Profiles by the agency of Light upon Nitrate of Silver. Invented by T. Wedgwood. With observations by H. Davy."

The female descendants of Josiah Wedgwood made their due contribution to science. Susannah ("Sukie") Wedgwood, a favourite of her father, married Robert Waring Darwin, the son of Erasmus Darwin.

The Wedgwood-Darwin pedigree shows the contribution to the realms of science made by these two illustrious families. The issue from this first Darwin-Wedgwood marriage gave to the nineteenth century no other than Charles Robert Darwin. He further embraced the Wedgwood family by marrying his cousin Emma, the daughter of the second Josiah Wedgwood. The fertile mind of Charles Darwin showed that in the nineteenth century he had inherited the remarkable scientific spirit and genius of his two grandfathers, both outstanding eighteenth century philosophers. The descendants of the Prince of Potters have preserved the remarkably fine features of their

illustrious ancestor Charles Robert Darwin in a fine plaque which now hangs in his room in Christ's College, Cambridge.

In conclusion, may I apply to the Prince of Potters who has inspired this discourse, words once spoken of Sir Humphry Davy by Samuel

Taylor Coleridge, Thomas Wedgwood's bosom friend, who said: "If Davy had not been the first Chemist, he would have been the first Poet of his Age." We can equally declare: "If Josiah Wedgwood had not been the first Potter, he would have been the first Scientist of his Age."

Obituary Notices

Prof. Victor Grégoire

THE death of Prof. Victor Grégoire on December 12 removes one who was not only a leader among the cytologists of his time but was also one who, as a botanist, was deeply concerned with problems of plant morphology and applied essentially cytological methods to their solution. Especially in the pre-War period, his influence in cytology was wide and many of his contributions were of fundamental importance. He was essentially an observer rather than a theorist, and although many of his best observations were on chromosome structure and behaviour he did not follow cytology far into its later intimate relations with genetics, although his pupil and colleague, Janssens, was the founder of the theory of chiasmata.

In more recent years, Grégoire became deeply immersed in problems of floral morphology, and an extensive memoir on the carpel (*La Cellule*, 47, part 3) which is the result of ten years of research, has recently appeared. This was intended to be the first of a series of contributions setting forth his views, based on extensive investigations of floral structures.

Grégoire was born at Anderlues, Belgium, on December 5, 1870. From 1887 until 1894 he studied philosophy and theology in Rome. The following year he returned to Belgium and studied science at Louvain for three years under Carnoy. In 1897 he became assistant in botany and in 1899, after two further years of foreign study, he was appointed extraordinary professor of botany, succeeding to the professorship of cytology and botany at the Carnoy Institute in 1903. The rest of his life was spent as a professor in the Catholic University of Louvain. He always adhered to his priestly robes, and he showed outstanding courage during the occupation of Louvain in the Great War. In 1925, the twenty-fifth anniversary of his professoriate was celebrated and two jubilee volumes of *La Cellule* (of which he became co-editor in 1928) were published. These consisted of contributions from his former students, many of whom had visited his laboratory from foreign countries in Europe and the United States.

Grégoire spoke with great clarity of diction and taught with vigour and enthusiasm. A man of very gentle disposition, he lived a very quiet life in a quaint old house of eighteenth-century Flemish style, completely absorbed in his scientific work. In some respects he might be regarded as the counterpart of Mendel in modern life; but in his view, as expressed

in 1925, he limited Mendelian behaviour to varieties and held that specific differences were non-mutational in origin and non-Mendelian in inheritance.

Nearly all the more important publications of Grégoire appeared in *La Cellule*. His first paper (1899) was an extensive memoir on the pollen meiosis in Liliaceae. He concluded that the spireme thread (peloton) divides first longitudinally into two interlaced threads and then transversely into twelve chromosomes, which are therefore constituted of two longitudinal halves. But this is not the place to enter in any detail into the intricate history of the development of ideas regarding meiosis.

In 1903, in collaboration with his pupil Wygaerts, Grégoire made a careful study of the events of telophase in root-tips as regards the history of the chromosomes and their transformation into the resting nucleus. These papers immediately gave him a deservedly high reputation as an observer. The phenomena of meiosis shortly reclaimed his attention, and a series of memoirs followed until 1916 on various aspects of mitosis and meiosis in plants and animals. Several of these were extensive critiques of the current literature. In 1905 he concluded that if there was a real reduction division of the chromosomes it must be the first division. In 1907 he introduced the term zygotene for the stage in which the threads pair longitudinally to form a thick spireme or pachytene nucleus. (Dr. C. D. Darlington's suggestion in *NATURE* of February 4, p. 206, that my first paper (1907) was responsible for the conception of the continuous spireme in pollen mother cells is therefore erroneous, because the conception was current if not universal for some years before my work was begun.) By 1910 he had clearly adopted parasynaptic pairing at the zygotene stage as characteristic of meiosis in plants and animals generally.

In the post-War period, Grégoire transferred his main interest to other fields of botany. He published several text-books dealing with general botany, anatomy and the systematics of angiosperms, only once returning to cytology, in a paper on chromocentres in plants, although many cytological papers continued to appear from his laboratory.

In recent years, the nature and origin of the carpel has been the subject of much investigation, and many diverse views and theories of its morphology have been propounded. Grégoire's extensive memoir on this subject adds a different view. Having discarded the classical theory of its leaf-like nature, he also

disagrees with all the views recently propounded. He concludes from a detailed comparison of stem-tips and floral receptacles in many plants that the vegetative cone and the floral apex are independent structures, carpels not arising from the latter in the way that leaves arise from the former. He held the view that the carpel, as a reproductive structure, was an organ *sui generis*, not to be homologized with any purely vegetative structure such as a leaf. His work will doubtless lead to further discussion of this intricate problem.

During his relatively uneventful but scientifically active life Grégoire received many honours. He was a member of the Royal Academy of Belgium, the Paris Academy of Sciences, the Pontifical Academy of Sciences and the Royal Irish Academy, and had received honorary degrees from various universities. He was elected a foreign member of the Linnean Society in 1917 and an honorary fellow of the Royal Microscopical Society in 1931.

I am indebted to Profs. Martens, Robyns and McLean Thompson for several of the facts here recorded relative to the life of Grégoire.

R. RUGGLES GATES.

Dr. C. J. Gahan

DR. C. J. GAHAN, who died on January 21, the day after attaining his seventy-seventh birthday, was for thirteen years keeper of the Department of Entomology of the British Museum (Natural History) and was in charge of the enormous collection of insects at South Kensington from 1910, when he succeeded the late Charles Owen Waterhouse as assistant-keeper in charge of that section of the Department of Zoology, until his retirement from the Museum in 1926. Increasing recognition of the importance of entomology led to the creation of a separate Department of Entomology in 1913 and Gahan was appointed its first keeper.

Charles Joseph Gahan was born at Roscrea, Tipperary, in 1862, the son of Michael Gahan, master of Erasmus Smith's School in that town. He was educated first in his father's school and afterwards at Queen's College, Galway (later of the National University of Ireland), from which he obtained the degree of M.A. and afterwards D.Sc. In 1884 he went to London and for two years studied science at the School of Mines (now the Royal College of Science), then presided over by Huxley. In 1896, he was appointed to an assistantship in the Department of Zoology of the British Museum (Natural History), which only six years previously had been removed to South Kensington. Although until that time he had made no special study of insects, his inclination having been chiefly in the direction of botany, it was the rapidly growing entomological collection, and especially the immense order of Coleoptera, to which he was to devote himself during the thirty years spent in the service of the Museum. In 1899 and 1900 he was secretary, and in 1917 and 1918 president, of the Entomological Society of London.

Of Gahan's numerous published writings most are upon the timber-destroying family of beetles, the

Cerambycidae, upon which he became the leading authority. He also devoted considerable attention to the problem of dealing with the depredations of the death-watch beetle and the closely related furniture-beetles, and was the author of a valuable booklet published by the Museum on the subject. Other subjects to which he made original contributions were mimicry in insects and the vocal and auditory organs of the Coleoptera. Although never a keen collector, he was by no means an arm-chair naturalist, but took the greatest delight in the study of living creatures. He was also an enthusiastic horticulturist and, being cut off by persistent ill-health from the means of continuing his former pursuits, he devoted much of the last twelve years of his life to the cultivation of a large garden at Aylsham, in Norfolk, where he lived from the time of his retirement. He leaves five sons and two daughters.

GILBERT J. ARROW.

Prof. M. W. Pavlova

PROF. M. W. Pavlova (Marie Pavlov), professor of palaeontology in the University of Moscow, died on December 20 at the age of eighty-four years.

A pioneer of the progressive movement among women of old Russia, she was educated abroad. She was a pupil of the French palaeontologist Albert Gaudry, and introduced the principles of his school into her native country and trained several generations of Russian palaeontologists, particularly women.

After Woldemar Kowalevsky, whose chair she held in the University of Moscow, Marie Pavlov was the founder in Russia of palaeontology as a biological science. Full of energy and activity, she frequented the museums of her country and described in her valuable monographs the collections of fossil mammals hidden in these museums. Similar fossils were studied by her abroad in various European and American museums. She was thus able to draw the generalized conclusions in her "Études sur l'histoire paléontologique des ongulés" for the various groups of ungulates, namely, horses, rhinoceroses, artiodactyles and proboscidea. Having worked a great deal in foreign museums she made friends with the foremost palaeontologists of the world. Her name was one of the best known among foreign naturalists.

Marie Pavlov considerably extended the palaeontological material left by W. Kowalevsky in the University of Moscow, and together with her husband, the late professor of geology, A. P. Pavlov, created one of the best palaeontological museums in the U.S.S.R., which now forms part of the Moscow Geological Institute.

A. BORISSIAK.

We regret to announce the following deaths:

Dr. L. H. Dudley Buxton, fellow and bursar of Exeter College and reader in physical anthropology in the University of Oxford, on March 5, aged forty-nine years.

Mr. Howard Carter, known for his work in Egyptology, especially in connexion with the tomb of Tutankhamen, on March 2, aged sixty-five years.

News and Views

Prof. E. H. Minns, F.B.A.

PROF. ELLIS HOVELL MINNS will retire shortly from the Disney professorship of archaeology in the University of Cambridge, which he has held since 1927, when he succeeded the late Sir William Ridgway. Prof. Minns has been a fellow of Pembroke College, Cambridge, of which he had been an undergraduate, since 1899, and became president in 1928. After taking his degree at Cambridge he studied Oriental languages in Paris, and spent three years in Russia, studying its languages, history, art and antiquities. On his return to Cambridge in 1901 he was appointed librarian and lecturer in Russian in his college, and in 1906 became University lecturer in palaeography. As an archaeologist he is best known for his pre-eminence as an authority on the peoples and cultures of ancient Scythia, upon which his "Scythians and Greeks", published in 1913, is of outstanding value. His services to this branch of archaeological studies was recognized by his election in 1925 as a corresponding member of the Russian Academy for the History of Material Culture. Prof. Minns is a fellow of the British Academy; and during the Great War his linguistic abilities were recognized by his appointment to the censorship of uncommon languages, which he held from 1915 until 1918.

New Autogyro for Army Service

A DEMONSTRATION of vertical take-off and landing by the new type C.40 Autogyro, referred to as the 'jumping gyro', was given recently at the Army Staff College, Camberley. Mr. Brie made several successful take-offs and landings on the Owl's cricket ground, which measures only 150 yards by 100 yards and is almost entirely surrounded by buildings and high trees. In addition to making vertical rises from the ground of 8-10 ft., the machine was put through a series of evolutions in the air illustrating its control and ease of handling in a confined space. The most outstanding of these was an entirely unintentional one at the close of the display, when the pilot, judging that he had not sufficient margin to clear some trees, throttled his engine back and put the machine down almost exactly upon the spot from which he had started. Such a manoeuvre would have been impossible with the more conventional type of aeroplane. This display, given on a bad day with intermittent rain causing inevitable air currents and eddies near the ground, is considered to be a much more searching test of the machine's controllability than was the recent test of a direct-lift helicopter made in a big hall in Berlin. Although flying in a building gave an appearance of complete control in a very confined space, actually the steady performance of the machine would be materially helped by the perfect calmness of the air indoors. It is considered that this type of machine will facilitate the work of Army communication by reason of the fact that, requiring practically

no horizontal run, it is independent of the condition of the landing surface. Not only will it not need a specially prepared aerodrome, but it should also be able to operate from land where even shelling or bombing has been experienced. It is also obviously suited to operating from the deck of a ship.

Leopold Gmelin and his "Handbuch"

To commemorate the hundred and fiftieth anniversary of the birth of Leopold Gmelin, the Deutsche chemische Gesellschaft has issued a sample booklet with lengthy extracts from the "Handbuch" and an illustrated brochure with Gmelin's portrait and historical notes on the growth of this monumental treatise. Gmelin belonged to an ancient Swabian family of apothecaries established in the seventeenth century at Tübingen, where his grandfather held the University chair of chemistry, one of the oldest in Germany. His father became professor of botany and chemistry at Göttingen, where Leopold was born on August 2, 1788. After graduating in the faculty of Medicine at Göttingen, he studied chemistry at Tübingen and in Vienna. Later he travelled in Italy, where he interested himself in the geology of the volcanic rocks, but his chief interest lay in chemistry, and he decided to complete his training in Vauquelin's laboratory in Paris and at the same time make personal contacts with Gay-Lussac, Thenard and Haüy. In 1817, he was appointed to the chair of chemistry at Heidelberg, where he began to write his treatise, the first edition appearing in three volumes in 1817. It met with immediate success, and several editions had to follow. In 1830, Berzelius praised it in glowing terms. The fourth edition was translated into English by the Cavendish Society in 1846, and included organic chemistry for the last time. Gmelin was occupied with the organic part until his death in 1853. The eighth edition, begun in 1922, is at present being compiled by no fewer than seventy experts, who expect to finish their task by 1943 and to secure a lasting future for this valuable documentation. Both the sample booklet and the brochure may be obtained free on application to the Gmelin-Redaktion, Berlin W.35, Tiergartenstrasse 10.

Ornithological Library for Australia

It has recently been announced that Mr. G. M. Mathews has presented his ornithological library to the Commonwealth of Australia, and that it will be housed in the National Library at Canberra. Mr. Mathews, who is the author of twelve large volumes on the "Birds of Australia", has been collecting books on ornithology for the last forty years, and his library consists of some four thousand works and pamphlets. Although many ornithologists may not agree with Mr. Mathews' systematic work as a whole, all will admit that he has done more than anyone to elucidate the early history of ornithology in Australia. He has

specialized in the works of early voyagers to the southern hemisphere in which there is any mention of birds, and his collection includes a copy of that very rare book published in 1701 by William de Vlaming, a "Journal of a Voyage to the Unexplored Southland . . . in 1696 and 1697". Of books on Australian birds, there is a complete set of all the editions of Lewin's "Birds of New Holland", starting with the first, published in 1808, of which there are only six known copies. Gould's great folio-work is of special interest, since it includes the two parts published before the author went to Australia and afterwards withdrawn and replaced, after his return.

SINCE Mr. Mathews takes a great interest in nomenclature, his library naturally includes many rare and little-known general works. Among these may be mentioned Vroeg's "Catalogue" (1764), and Boddaert's "Table des Planches Enluminées" (1783), the former not included in the British Museum's (Natural History) library, and the latter only represented by a photostat copy and a reprint. Other rare and interesting books include Rafinesque's works (1814-22), Berthold's edition of "Natürliche Familien des Thierreich" by Latreille (1827), and Moehring's "Avium Genera" (1752). There are complete sets of certain periodicals such as the *Isis*, and more particularly of local journals published in Australia, including the first volume of the Queensland Philosophical Society, which is said to be unique. After having completed his "Birds of Australia", Mr. Mathews brought out an additional volume of bibliography, and, with a few exceptions, all the books mentioned therein are in his possession. The acquisition of this library should now enable students in Australia to study ornithology independently of the libraries in Europe and elsewhere.

Nutritional and Allied Aspects of Milk

It has already been announced that the new Division for the Social and International Relations of Science of the British Association is arranging a meeting for the discussion of this subject to be held on March 28 at the University of Reading. Representatives of a number of interested public bodies and institutions will be present. The meeting will be divided into two sessions, lasting from 2.15 to 4.15 and from 5.15 to 7.0, with an interval for tea. At the first session the chair will be taken by Sir Richard Gregory, chairman of the Division. Dr. Harriette Chick will open the discussion, dealing with deficiencies in present-day diet, the total amount of milk needed, etc., Prof. J. O. Drummond will discuss health aspects, and Dr. A. W. Scott will speak on the implications of compulsory pasteurization. At the second session, Sir Daniel Hall will be in the chair. Mr. J. MacKintosh will discuss agricultural aspects of milk production, with special reference to increase of production, and Mr. J. Cripps will speak on the distribution, cost and the economic and social implications allied with the subject. The meeting will be preceded, in the morning, by a visit to the National Institute for Research in Dairying at Shinfield, near Reading. Arrangements will be made for

lunch, tea and dinner to be served in the University so far as accommodation permits, and accommodation for the night preceding the meeting may be arranged if a sufficient number desire it. Admission will be free, by ticket. A limited number of tickets will be obtainable from the Secretary, British Association, Burlington House, London, W.1.

The Institute of Chemistry

At the sixty-first annual general meeting of the Institute of Chemistry held on March 1, Sir Robert Pickard, the retiring president, directed attention to the fact that the membership now consists of more than 7,200 qualified chemists. The Council is endeavouring to obtain the consent of the fellows and associates to a petition for a supplemental charter embodying a scheme for the registration of those chemists whose qualifications are the same as those required for admission to the Institute, but who do not wish to become fully associated with its work. It is, in Sir Robert's view, a scheme proposed in the best interests of the Institute, of the profession as a whole, and of the State. Sir Robert referred to the possible utilization of the services of chemists in any national emergency. The position of the country, so far as the supply of chemists and the condition of the chemical industries are concerned, is very different from that of twenty-five years ago; but war usually brings unexpected demands, and chemists will be glad to know that an organized effort is being made which will direct their skill and willingness to serve the country into the most advantageous channels. The Institute is fortunate that, in times like the present, less than 1.2 per cent of its members are known to be without employment, and only a small proportion of those has been unemployed for any long period. Sir Robert directed attention to the third annual report of the Chemical Council, recently published. This body, on which the Institute is represented, has under consideration a scheme the object of which is to distribute the burden of the cost of publications of the Chemical Society and the Society of Chemical Industry more equitably over the membership of all three chartered chemical bodies. The Meldola Medal, the gift of the Society of Maccabaeans, has been awarded to Dr. William Charles Price. The following officers for 1939-40 have been elected: *President*, Mr. W. A. S. Calder; *Vice-Presidents*, Dr. H. V. A. Briscoe, Dr. F. H. Carr, Dr. T. P. Hilditch, Mr. G. Roche Lynch, Dr. C. Ainsworth Mitchell, and Sir Robert Pickard; *Hon. Treasurer*, Mr. B. F. Howard.

Society of Public Analysts and Other Analytical Chemists

At the annual general meeting of the Society of Public Analysts and Other Analytical Chemists held on March 3, the following officers were elected for the year 1939-40: *President*, Prof. W. H. Roberts; *Vice-Presidents*, E. B. Anderson, J. R. Nicholls, W. H. Simmons, T. P. Hilditch (chairman, North of England Section), T. Cockburn (chairman, Scottish Section); *Hon. Treasurer*, E. B. Hughes; *Hon. Secretary*, Lewis Eynon. Following the annual

general meeting, a lecture was delivered by Sir Henry Dale on "Biological Standardization". Sir Henry outlined the history of the establishment of standards for the biological assay of preparations of physiologically active products such as antitoxins, hormones, vitamins, etc. Attempts to set up units in terms of physiological effects under particular experimental conditions ('rat units', 'mouse units', etc.) have led to wide discrepancies and great confusion, owing largely to the difficulty of reproducing the conditions under which the proposed units were first determined. Following the pioneer work of Paul Ehrlich, the systematic establishment of international 'units of activity' based on stable standard preparations of the active substances was begun under the auspices of the Health Organisation of the League of Nations in 1921, and a number of these standards have been prepared at the State Serum Institute, Copenhagen. Standards for a still larger number of products have more recently been prepared in Great Britain at the National Institute for Medical Research, Hampstead. A general account was given on these developments and some particulars of the standard preparations now available.

A Bird-watcher's Experiences

In a lecture to the University of London Animal Welfare Society, at Bedford College on March 8, Mr. Eric Hardy, of the British Empire Naturalists' Association, spoke of his experiences as a bird-watcher in various parts of Great Britain. He mentioned how a day-by-day census and survey of the sparrow population of the Liverpool Cathedral Birds' Sanctuary, in the heart of city slums eight miles from open country, failed to prove any great migration out of the city to country harvest fields as is often supposed, although many other migrants, chiefly warblers, passing over the city, use the sanctuary as a resting-place. This famous little sanctuary is to be reconstructed and re-equipped this year by the Merseyside Branch of the British Empire Naturalists' Association, which will be its custodian in the future. Mr. Hardy gave his experiences of the increasing numbers of buzzards and ravens in Wales, how swifts and tawny owls are among the birds adapting themselves to life in growing towns, even in the industrial north. The annual May shooting of baby rooks in the nest is a cruel sport, he said, and even apart from that question, field-studies show that unless rooks are in abnormal numbers, they do more good than harm on the land. The habit of taking regular censuses of bird numbers in various areas has added considerably to our knowledge of bird movements and migrations, especially with shore birds.

Archæological Excavations in Cornwall

RELICS obtained from excavations on a Late Bronze and Iron Age site in the Great Gear Field at Carwarthen, St. Just-in-Roseland, Cornwall, are now on exhibition in the museum of the Royal Cornwall Polytechnic Society at Falmouth. These excavations have been carried out during the past year

under the direction of Mr. S. A. Opie of Redruth. The site, it would appear from an account of the excavations in the *Royal Cornwall Gazette and County News* of February 22, was occupied from 1000 B.C. onward. In the earlier phases of its occupation, it is the first to be identified in Cornwall as dating from the important Late Bronze Age period, to which belong the earliest classical references to the Western tin trade. The site is thus of unusual interest and importance; while in view of the small area as yet explored, it is the richest and most productive of the period of its later occupation as yet examined in Cornwall. A fair amount of bronze age pottery, some with cordon and finger-tip impressions, has been recovered; but as yet no traces of structural remains of the early period have been found. A small circular fortification belongs to a later occupation, being of a usual iron age type. Of this, the position of the circular ditch has been established at six points where it is from six to ten feet deep. Stone revetments of the inner face of the ditch have been found at five points. The ramparts, much damaged by ploughing, afford evidence of several periods of construction. At the best preserved section, there are three successive stone revetments, and clear evidence of an interior wall walk. The iron age pottery is mostly late, being attributed to the first century A.D. or at oldest to the first century B.C. None of the fine decorated pottery of the second century B.C., such as has been found at Glastonbury or Castle Dore, has appeared. The site was extensively occupied in Roman times down to the fourth century. Native pottery betrays Roman influence, while two pieces of Samian of the second century A.D. and two of New Forest wares of the fourth century A.D. have been unearthed. Coins, numerous fragments of iron implements, perforated slate disks and a waisted stone hammer have also been found. The excavations are to be continued.

Electric Generators at Boulder Dam

DURING 1938, *Engineering* published a series of articles dealing with the remarkable work being carried out at Boulder Dam, Arizona. This project has a three-fold purpose—flood control, storage of water for irrigation and domestic and industrial use, and the generation of electric power. There are two power-houses, the Nevada wing and the Arizona wing, and the series of articles referred to is brought to a close by a description of the electrical equipment being installed in these. The two articles on this subject are by Mr. L. N. McClellan, and were published in *Engineering* for February 10 and 24. There will ultimately be eight large units of 82,500 k.v.a. in the Nevada wing and seven similar units and two units of 40,000 k.v.a. in the Arizona wing; the hydraulic turbines driving the larger units being of 115,000 h.p. Each of the 82,500 k.v.a. generators is 40 ft. in diameter, 32 ft. in height above ground-level and weighs approximately 900 long tons. The stator frames are constructed entirely of steel plates and structural shapes electrically welded together. The rotors are 25 ft. in diameter, 8 ft. deep at the rim, and are carried in shafts 38 in. in diameter and

36 ft. long. Each weighs approximately 580 tons. One group of machines will furnish power for the pumping plants on the Colorado River, supplying the Metropolitan Water District, a second group will supply the cities of Los Angeles, Burbank, Glendale and Pasadena, a third the Southern California Edison Company, and a fourth will supply power to the States of Arizona and Nevada. With the service station generators the ultimate capacity of the plant will be 1,323,500 k.v.a.

The Indian Journal of Pharmacy

SOMEONE has proceeded apace in India, especially since the Great War, and this progress has seen marked improvement in India's scientific publications and the initiation of new journals of international importance. Now, we are pleased to welcome another addition to the list, namely, the *Indian Journal of Pharmacy*, the official publication of the United Provinces Pharmaceutical Association (1, No. 1, Jan.-March, 1939. The Secretary, U.P. Pharmaceutical Association, Department of Pharmaceutics, Benares Hindu University. Rs. 3s., India; Rs. 4s. abroad annually). The *Journal* is being edited by Prof. M. L. Schroff with the help of a strong editorial board. It has a format similar to that of most other Indian scientific periodicals, and this number contains fifty pages. It opens with an editorial explaining the aims of the U.P. Pharmaceutical Association and its *Journal*, which leads on to a review of pharmacy in other countries. Then follows an article on "Diet in Relation to Copper for Infants" by Dr. U. P. Basu; another specialized article, by Prof. M. L. Schroff and M. Lal Dhir, deals with the "Assay of Kurchi and Kurchi-Bismuth-Iodide". More general articles deal with the medicinal, aromatic and allied plants of Egypt, the medicinal plants of Kashmir and the treatment of burns. Notes and news, abstracts, reviews and proceedings of the Association complete the number. It would be ungracious to point out ordinary slips in the printing of the *Journal*, but the typography might well be improved. We sympathize with the *Journal's* plea for the establishment of an Indian Pharmacopoeia.

An Educational Co-operative Colony

ON the initiative of Sir Akbar Hydari, the Chancellor of the Osmania University and President of the State Council, Hyderabad (Deccan), an attempt is being made to demonstrate the suitability for adoption on a large scale of a plan for part-time education in association with co-operative production for use. This enterprise is being conducted under the auspices of the Hyderabad State Co-operative Department and is under the management of Captain J. W. Petavel, who has for many years devoted his energies to the advocacy of similar schemes in connexion with the University of Calcutta, propaganda inaugurated by the late Sir Asutosh Mookerjee for educational colonies. For the new scheme, buildings and twelve acres of land belonging to the Osmania University have been made available, and it is hoped that undergraduates will take advantage of

the opportunity to train for educational colonies work. It is intended to establish another and much larger colony in an irrigated tract. The general idea of the educational colony is to form the children and adolescents for educative employment in colonies organized for co-ordinated production of food and other necessities of life. The child's day would be divided between "really good production work, good games and class work" in approximately equal shares. Special features of the new scheme are to be: employment of well-trained adolescents under the guidance of a few adults to supervise the children, co-operation between capitalists and workers for production for use, and an extensive use of labour-saving methods.

Earthquake in the Solomon Islands

AN earthquake of sufficient intensity to affect seismographs in all parts of the world occurred on January 30 at 2h. 18m. 31s. G.C.T. No news of any earthquake damage was reported from any place at this time, and by instrumental records from thirty-two stations alone E. Peterschmitt, at Strasbourg, has determined a provisional epicentre at latitude 6° S., longitude 156° E. This is near the Solomon Islands, a well-known seismic centre. It was from an epicentre to the south-east of this, namely, 9° S., 159.5° E., that a very severe earthquake occurred on January 25, 1926, ruining the catholic church at Visale, doing very severe damage to property and causing severe casualties. In October 1931, again, earthquakes with epicentres 14° S., 160° E., and 8° S., 160° E., did severe damage on several islands. At San Cristoval two villages were razed by the first earthquake and eighteen villages on the southern coast were afterwards swept away by a sea wave 30-40 ft. high. For the 1939 shock the seismogram at Stuttgart included e_2P , 2h. 34m. 24s., i_2P' , 2h. 37m. 39s., (dilatation), $iPKS$, 2h. 41m. 2s.; eL , 3h. 16m. ($T = 50s.$); MQ , 3h. 26.5m. ($T = 22s.$) and MR , 3h. 38.5m. ($T = 20s.$) all in G.C.T.

Central and South American Earthquakes

ON the basis of reports from the seismographic stations at Georgetown, Fordham, Huanacayo and San Juan, the U.S. Coast and Geodetic Survey in co-operation with Science Service and the Jesuit Seismological Association has determined the epicentre of the earthquake of February 9, 1939, at 15h. 30.5m. G.C.T. to be provisionally latitude 11.5° N., longitude 88° W. This epicentre is in the Pacific Ocean to the west-south-west of Managua, the capital of Nicaragua, which was almost completely destroyed in the earthquake of March 31, 1931. The epicentre nearest to the present one in recent years was on February 15, 1926, when the epicentre was 11.7° N., 89.8° W. No damage has been reported in the present instance. Following recent shocks, the town of Cumbaya, near Quito, was strongly shaken during the night of March 2, by an earthquake which cracked many buildings, and caused apprehension amongst the inhabitants. No casualties are reported. It was on February 7, 1797, that Quito was destroyed by earthquake with the loss of 40,000 lives. On

October 2, 1938, another part of Ecuador, namely, the Santa Elena Peninsula, was strongly shaken by an earthquake. Weak local shocks often occur in the area.

Michael Scot: Pioneer of Science

PROF. J. READ has contributed an interesting study of "Michael Scot: a Scottish Pioneer of Science" to *Scientia* (Oct.-Nov. 1938). Michael Scot lived in the early part of the thirteenth century and worked as a translator of Arabic writings in Spain and Sicily, where he was court astrologer and philosopher to the Emperor Frederick II. In later times he acquired the reputation of a magician and necromancer, and many legends have gathered around his name. Although our knowledge of him is fragmentary, Prof. Read shows that Michael Scot was a man of genuine scientific interests. His views on alchemy are interesting, since it is significant that he mentions neither transmutation nor the philosopher's stone, so that he followed the Greek-Egyptian sources rather than the later authors of western Europe. Of his other works, Scot's "Physionomia" had an extensive circulation in manuscript for 250 years and afterwards in several printed editions. He also wrote on astronomy, astrology and the art of prediction, and stands out as the most eminent Briton to secure a place in the history of medieval Italy.

The Imperial Institute

THE annual report of the Imperial Institute (South Kensington, London, S.W.7) for 1938 shows that an important side of the work of the Institute lies in the research departments which answer an increasing number of inquiries from all parts of the Empire. Queries concern both seeds and roots of economic value and various mineral samples. The Mineral Resources Department was particularly active and reported on samples from various colonies. Special interest attaches to the demand for high grade quartz crystals for both piezo-electric and optical purposes, but so far the search for new sources of this material has had little success. The oxide of titanium known as rutile which is used in the coating of electric welding rods has been found in various parts of the Empire. Many other examples of the usefulness of the Institute are recorded in this report.

A Virus Disease of the Elm

AMERICAN elm trees in the Ohio valley are subject to a new and deadly virus disease which is briefly described in a mail report from Science Service, Washington (Feb. 4, 1939). Leaves upon infected trees first shrivel and become brittle, then the roots and inner bark of the trunk rot away, and the tree dies within a few months. This is the first known instance where a virus disease has caused a fatal epidemic among trees. The outbreak appears to be even more serious than that of the so-called Dutch elm disease which has decimated elm trees in the neighbourhood of New York. It is reported that more than 1,000 out of about 1,800 elms in one particular locality have been killed by the virus

during three years. Means of dissemination of the pathogen have not yet been found, but the United States Division of Forest Pathology is taking energetic measures to trace the extent of the infection, and to limit it to one district, if possible.

Use of Electricity in Coal Mines

ON the recommendation of the Royal Commission on Safety in Coal Mines, the Secretary for Mines has appointed a Committee with the following terms of reference: "To be a committee to consider, in the light of experience and modern practice, what amendments are required in the General Regulations governing the use of electricity below ground and above ground at mines under the Coal Mines Act, 1911, taking into consideration the report of the Royal Commission on Safety in Coal Mines and the evidence on the subject submitted to that Commission". The following are members of the Committee: Prof. W. Cramp, Department of Electrical Engineering, University of Birmingham (chairman); Mr. J. A. B. Horsley, H.M. Electrical Inspector of Mines; Mr. A. M. Bell and Mr. A. B. Connell. The secretary to the Committee is Mr. R. Crawford, Mines Department, Mill House, 87-89 Shaftesbury Avenue, London, W.1.

Chemical Society Anniversary Meetings

THE anniversary meetings of the Chemical Society this year are to take place in London on March 29-31. On March 29 the Rutherford Memorial Lecture will be delivered by Sir Henry T. Tizard at the Royal Institution at 5 p.m., and fellows and guests will be entertained at a reception and dance at Imperial Chemical House from 8.45 until midnight. On Thursday, March 30, visits have been arranged in the morning to Bedford College for Women and to the Wellcome Research Institution, to view the laboratories and museums. The annual general meeting will be held at Burlington House at 2.30 p.m., and at 4 p.m. the presentation of the Longstaff Medal and of the Harrison Memorial Prize will be made and Prof. F. G. Donnan will give his presidential address. The anniversary dinner of the Society will be held at Grosvenor House the same evening at 7 for 7.30 p.m. On Friday, March 31, visits have been arranged in the morning to The British Drug Houses, Ltd., and to the Central Laboratories of the Shell Marketing Co., Ltd., and in the afternoon to the Research and Development Department of the Distillers' Company, Ltd. at Epsom, and to the laboratories of the Research Association of British Paint, Colour, and Varnish Manufacturers.

Royal Society of Edinburgh: Elections

AT the ordinary meeting of the Royal Society of Edinburgh, held on March 6, the following ordinary fellows were elected: Prof. Arthur B. P. Amies, Australian College of Dentistry, Melbourne; Dr. William G. Annan, Clinical Medical Officer, Durham County Council, Darlington; Prof. J. H. Baxter, Department of Ecclesiastical History, University of

REVIEWS

Arthur Young, F.R.S. : Farmer

Sheep and Turnips

Being the Life and Times of Arthur Young, F.R.S., First Secretary to the Board of Agriculture. By Amelia Defries. Pp. xviii+235. (London: Methuen and Co., Ltd., 1938.) 7s. 6d. net.

ANALOGIES between the agricultural conditions in the later years of the eighteenth century and those of to-day render opportune the publication of this study of Arthur Young. Agriculture at both periods was depressed. Countrymen were flocking to the towns, and the land was being neglected and allowed to become derelict. A revolution in farming practice, coupled with the introduction of new crops, is to be contrasted with possible methods to-day, very different in that no new bulk-feed or other crops are being advocated. There was a fight to combat the food-shortage and high taxes of the Napoleonic period, as there was in the Great War—and must be in all future wars. The enclosure of lands—twenty-two million acres during Young's period—allowed the development of arable farming for corn, while the growth of winter feed, especially turnips, encouraged the carrying over of stock from year to year and eliminated salt meat from our dietary. The introduction of cabbage, the popularization of potatoes and the regular use of clover assisted in producing an alternation of crops and were thus of importance. To-day, in contrast, we have a huge manufacturing population to be fed, while much land has gone out of cultivation, and many farms show increasingly depleted and weedy soils which only an evolution in scientific practice or a revolution in the attitude of the State can rectify.

The change-over of the eighteenth century was mainly due to three men, Coke, Sinclair and Young, aided by the interest of King (Farmer) George. Coke carried out vast enterprises in Norfolk with

financial success; coupled with these was a great improvement in the social life of his region, enclosure and high farming increasing its population threefold. Sinclair opened up his large estate in Scotland by roads, enclosing where he could—and statistically examined his country's agriculture in respect to population.

Young, born in 1741, son of a Suffolk vicar, who was also a fashionable clergyman in London, being chaplain to the Speaker, was the dominant influence. His mother was a Jewess. His 'polite' education was scanty, the extravagance of his father temporarily reducing him to the lower social grade of a farmer. By his pamphlets, often political, he procured money to buy books and soon took charge of one of his mother's farms in Suffolk. After four years, he recounted his experiences in a series of 'Farmer's Letters to the People of England', also meditating on the ways to harmonize agriculture and manufacture. "What vast employment the Enclosing gives . . . constantly keeping fences, ditches, gates, styles, bridges, in order, and . . . converting the wastes into arable farms . . . the numbers requisite for tillage . . . the numbers of manufactures . . . hides increasing amazingly . . . causing cheapness of bread".

In the next five years, Young published 'Farmer's Tours through the South, North and East of England', meantime cultivating a new farm which showed little profit as it was used for thousands of experiments. He was ever in want of money, though at times his writing, at ten shillings a page, was considerable—later as farmer-journalist to the *Morning Post* at five guineas a week. His fame was growing, and in 1774 he was elected to the Royal Society. As a diversion, he made a highly successful Irish tour. A legacy relieved him, and he commenced his great undertaking, 'The Annals of Agriculture', to which that

great "Briton"—he coined the word—Ralph Robinson (Geo. III) contributed, advocating clover, turnips and rye as fallow crops, more than paid for by the dung of the cattle which fed on them. Then in 1787–89 succeeded a series of French tours in two volumes, which with all his works was published by the Directory in twenty volumes, these forming the basis for all subsequent agriculture in France. Young was now famous, the revolutionist-reviver of land prosperity, and his methods were being universally studied. George Washington was his regular correspondent, and the Empress Catharine sought his advice. In 1793, Pitt created the Board of Agriculture of which Young became secretary, thereafter to be concerned mainly with the provision of food in times of war. He died in 1820, this father of modern agriculture, still a poor man, blind but happy in the revival that farming was showing after twenty terrible years.

Historians (Trevelyan, Green and Rose) pay high tribute to this great Englishman—he was

also the founder of the Yeomanry—but we are rather concerned with his methods. That Humphry Davy was appointed by him to lecture on "The Connection of Chemistry with Vegetable Physiology", the following year becoming professor of chemistry to the Board, is indicative of his views. His experiments on the use of turnips, potatoes, carrots, onions, etc., were numerous, and he introduced chicory and "nursed" the cabbage. He was all this time trying out rotations of crops in relation to soils, also the production of manuring by natural methods *per head of stock*. There are studies on soils, the absorbing properties of earths and the considerations of air in the soil. All experimentation, even if of no immediate practical value, is "necessarily useful . . . a spur that instigates abler heads. . . ." Enough of this charming personage, a great writer and thinker, student of the world, its society, its politics, its pleasures and its pains. A story to be recommended for our shelves.

J. S. GARDINER.

Air Raid Precautions

(1) A.R.P.

By J. B. S. Haldane. Pp. 296. (London: Victor Gollancz, Ltd., 1938.) 7s. 6d. net.

(2) Air Raid

The Technique of Silent Approach; High Explosive; Panic. By John Langdon-Davies. Pp. 142 + 32 plates. (London: George Routledge and Sons, Ltd., 1938.) 2s. 6d. net.

(3) Report of the Committee of the Institution of Structural Engineers on Air Raid Precautions

Pp. 48. (I.S.E., 1938.) 1s.

(4) A.R.P.

A Report on the Design, Equipment and Cost of Air-Raid Shelters. (Reprinted from *The Architects' Journal* for July 7, 1938.) Second edition. Pp. 15–48. (London: Association of Architects, Surveyors and Technical Assistants, 1938.) 1s.

THE disastrous effect of the gas attacks by Italian aircraft on the defenceless Abyssinians made such a profound impression on the equally unprepared people of Britain that the first air raid precautions in this country were heavily biased towards anti-gas measures. Then Japanese incendiary bombs on the inflammable areas of Chinese cities emphasized the importance of the fire-fighting services. But it is only recently that the deadliness of high explosive, as exemplified

in Spain, is being given its due weight. That this should be so seems strange, as there are still many men in England who have had first-hand knowledge of high explosive shells. A bomb only differs from a shell in that, weight for weight, it contains a greater percentage of explosive, and a heavy howitzer shell comes down from a height equal to that of Mount Everest. Given gas masks, the men who have faced it would infinitely prefer an attack by gas to one of equivalent weight of high explosive. For this reason, these two books, which deal with the general question of A.R.P. and the effect of high explosives in Spain, and the two professional reports on practical measures of protection, come as a useful corrective to our first obsessions.

(1) As might be expected from a man of his eminence, Prof. J. B. S. Haldane's is a masterly book, marred perhaps for some people by the political ingredient mixed with the main theme; and at times unworthy of his high level, as when jeers are made at the Home Office for its alleged solicitude for the pekes of Berkeley Square because in the "Householders' Handbook" people were advised to remove their pets. But whatever political opinions we hold, it is a book well worth reading. Clear, intensely interesting and with much of practical value.

On the subject of gas and bacteria, Prof. Haldane is reassuring. Most of the possible types of organic

compounds with small molecules have already been made. Mustard gas was discovered in 1886 and nothing worse had been produced by 1918. Since a poison gas must have small molecules, it is unlikely that more effective poison gases will be found. In theory, microbes might be used, but their general application is well-nigh impracticable and their use would probably be limited to producing panic fostered by rumour. With regard to the effect of gas, the casualties in the Hamburg disaster of 1928 are illuminating. A tank containing eleven tons of phosgene, one of the most deadly of war gases, burst without warning on a totally unprepared and unprotected population. Ten people were killed and about fifty made seriously ill. Prof. Haldane calculates that high explosives would be perhaps fifty times more deadly than gas. He therefore strongly advocates deep tunnels and shelters for the whole population of the target cities, at the huge cost of £400,000,000, and bases the need on the experiences of Barcelona.

It is difficult to arrive at the number of people in Barcelona for whom deep bomb-proof shelters have been provided. But on p. 40 Prof. Haldane mentions one-sixth of the population, and on p. 164 quotes Mr. Skinner that in May "there was shelter for about 240,000 people in brick-lined tunnels"; Prof. Haldane goes on to say, "I do not of course include trenches, cellars, underground railways or any of the types of shelters which are considered good enough for Londoners by our government". On the other hand, Mr. Langdon-Davies, writing in *The Times* in January 1939, states that Señor For, who was responsible for the A.R.P. in Barcelona, gave 30,000 as the maximum number of people who had protection against any type of existing bomb.

Complete protection, not only for people, but also for all vital plant, against bombs may be the ideal solution, but the money and time required are prohibitive. Splinter-proof protection gives a very large measure of security, and deep tunnels and concrete bomb-proof shelters are probably only practicable for certain essential-workers and vital plant.

(2) Mr. Langdon-Davies in his book "Air Raid" gives a very vivid picture with excellent photographs of the damage that has been done by high explosive bombs in Barcelona, and emphasizes the moral effect of terror and the material effect of blast. The terror was largely produced by the lack of warning and the terrific noise of the explosions. By applying the "Technique of Silent Approach", that is, the shallow dive from a great height with engines off, bombs were dropped on the city before the aircraft were detected and warning given. From this he deduces that similar attacks could be made on London.

It all sounds very creepy. The stealthy silent approach. The blow before you are aware of it. The gliding away in the darkness. But the shallow dive is a well-known method of attack. For places on or near the coast, like Barcelona or Hull, in the face of purely aural detection and in the absence of alert fighting aircraft, the manoeuvre is a definite menace. But there are three factors which must be taken into consideration when assessing its danger. The comparatively steep gliding angle of modern fast bombers with their small wing surface necessitates great initial height. To attain this, bombs or fuel must be sacrificed. Bombers must forgo their fighter escorts, and with their engines shut off they are easy prey for the defending fighters. London, with a balloon barrage to keep hostile aircraft up, is more likely to be troubled by an excess of warnings than by a lack of them. The 'silent approach' attacks on Barcelona soon ceased, and it is difficult to believe that the Nationalists would have given up this method if it was so successful, merely because the German and Italian airmen wanted to keep the manoeuvre secret for future and more important objectives.

On the effect of blast, Mr. Langdon-Davies is most interesting. Both the pressure and the suction waves caused great damage to windows, doors and the less substantial walls at a considerable distance. Historic monuments were being cased in outer walls which will not only protect them from splinters, but also in the event of a bomb falling nearby, the force of suction will be expended on the protecting wall.

(3 and 4) For detailed advice and practical measures of protection the two professional reports are very valuable. The Institution of Structural Engineers has published the first two parts of its A.R.P. Committee's report. These deal with the published information and the Committee's recommendations for protecting existing buildings. The remaining two parts, on air raid shelters and new buildings, are to follow. The A.A.S. and T.A. report gives diagrams, tables of resistance and cost of both splinter and bomb-proof shelters. In suitable soil, tunnels appear to be the cheapest form that is bomb-proof. The need for accessibility is, however, stressed, and where this is essential, as in a factory of national importance, or where the cost is prohibitive, splinter-proof shelters give a very large measure of protection. With regard to basements, both reports tend to favour the Swiss standard for strengthening the floor directly above the basement against the collapse of the building. This is more than double the strength suggested in the British and German regulations, but no detailed calculations are given.

E. H. K.

Standardization of Colours

Horticultural Colour Chart

Issued by the British Colour Council in collaboration with the Royal Horticultural Society. Pp. vii + 100 plates. (London: Royal Horticultural Society, 1938.) 10s. to Fellows, 21s. to non-Fellows.

COLOUR perception plays a very large part in everyday human experience. Yet most of us are singularly unable to describe colours with exactness, or order them systematically. We find ourselves lacking a yardstick and an exact terminology.

It is possible to analyse and define quite accurately the colour of any object under a given illumination, in terms of relative intensities and wave-lengths of light. But this is a cumbersome business, requiring special apparatus and technical skill. For ordinary purposes, it is easier to fall back on the method of comparison, and a number of attempts to provide an orderly basis for colour comparisons have from time to time been made, by printing standard colour charts. The most notable and widely used of these have been the "Colour Standards" of Ridgeway and of Ostwald, the "Répertoire de Couleurs" of Dauthenay and collaborators, and the later "Dictionary of Colour Standards" of the British Colour Council.

Recently another colour chart, prepared under the general direction of the art director of the Colour Council, Mr. Robert F. Wilson, has been published. The new work is in general layout very similar to the "Répertoire de Couleurs", consisting of loose sheets of handy size ($9\frac{1}{4}$ in. $\times$ $6\frac{1}{4}$ in.), in a stiff case. Each sheet, of smooth and white-surfaced paper, gives the name of a colour in English, and its synonyms in Dutch, French, German, Italian, Latin, and Spanish; references to any equivalents in the four older standard charts mentioned above, and a short historical note on the colour or its name; and the colour itself, in four rectangular blocks of increasing depth of tone, down the right-hand side of the sheet, in some instances accompanied by the names of one or more flowers of corresponding colour.

The volume now under notice—a second is projected—deals only with spectrum colours, and omits all the hues, such as browns and greys, which the artist would recognize as admixtures of all three primary pigments. The first sixty-four sheets range in sequence from yellows through oranges and reds to purples, and on through blues and greens back to yellow again. These are very well done, and justify the claim that recent advances in the art of colour printing have permitted

increased accuracy of reproduction. To most eye sheets 15 and 16, Fire Red and Poppy Red, and perhaps also 47 and 48, Oriental and Enamel Blues show colours approaching one another almost to redundancy. The gardener will note that few examples of flowers in the pure blues can be given.

The remaining thirty-six sheets in the volume are related to certain of the first sixty-four, being either lighter or darker tones of selected hues, and they are numbered in a manner which expresses this relationship. These supplementary sheets are less happily inspired. The user will resent the imposition of fresh names for different depths or 'tones' of the same colour, for example, Cairo Red for paler Orange. This is in direct contradiction of the premise in the introductory notes to the chart, that "There will thus be but one colour name recognised for each hue". The extra name is the more unfortunate because there is actually a very considerable overlap of the colours on the two sheets, so that a given colour may be equally well matched, as, say, Orange, intermediate between the blocks 12/3 and 12/2 in tone, or Carrot Red, intermediate between 612/2 and 612/1 in tone. All the supplementary sheets show this unnecessary duplication of tones on the parent sheet, often only the first or last block extending beyond the range already shown. The amount of overlap is not even constant, being less, for example, between sheets 14 and 614, Nasturtium Red and Chinese Coral, than between sheets 609 and 609, Tangerine Orange and Apricot. In fact these supplementary sheets might very well have been omitted. The chart would certainly have been simpler and more convenient in use if the increased range of tone had been obtained by adding a fifth block of colour to the sixty-four primary sheets.

Trying out the chart leads to some interesting discoveries. It is perhaps not very surprising that a certain amount of colour-blindness should occur amongst one's friends, hitherto unsuspected by the afflicted themselves; or that there should be great variation in an individual's capacities for memorizing colour. But few people will believe that lemon yellow is a deeper tone of straw yellow and at first sight the heading "Lemon Yellow" on sheet 4 appears a misnomer. Actually the sheet will be found to include an excellent match for lemon rind; the slightly greenish yellow hue which the name conjures up for most of us is a reflection of the unripe condition in which we get so much of our fruit.

There are few flowers in bloom and most of those given on the sheets as "horticultural examples" are at the time of writing unobtainable. Where it has been possible to check the colours of the flowers quoted, using the methods and precautions suggested in the notes supplied with the chart, confirmation of the careful work of the compilers has been obtained. The common Yellow Jasmine (or at any rate the particular plants at hand) provides the exception, for its corollas certainly match Canary Yellow, 2/1, excellently, and Aureolin, 3/1, where *Jasminum nudiflorum* is given, less well.

The sponsors naturally intend this publication to be primarily a stimulus to the more exact description and recording of flower colours. It is too early to estimate how far this aim will be realized. The price of ten shillings is not prohibitive of fairly extensive use, which is as well, for it is plainly unreasonable to expect nurserymen to spend a good deal of time and trouble matching their wares to the chart, and describing them by

reference to it, unless a large proportion of their customers can be expected to possess it. (Some years ago a Continental house actually issued its own chart with its catalogue.) Only the cynical are likely to repine if, before this further onslaught of standardization, romantic fancy is driven from its stronghold in the seed, bulb, and plant catalogues. Where the columns of the gardening press are concerned, the matter is more debatable, for the precise quotation of "Saturn Red (H.C.C. 13/1)" instead of "resplendent flaming orange" would inevitably mean a sacrifice of readability.

The chart will, however, be of utility in a much wider field than horticulture. Many chemists and biologists, especially ecologists, will find it of great value. To the dye, paint, and pigment trades and the textile industries it should be very welcome, although the latter, in particular, will still find the varying texture of surfaces a considerable handicap when colours are being matched.

SAMPSON CLAY.

Debatable Points of Animal Ecology

Problems of Animal Ecology

By Prof. F. S. Bodenheimer. Pp. vii+184. (London: Oxford University Press, 1938). 12s. 6d. net.

THE science of animal ecology is young, but is rapidly developing, and it is not surprising that its high rate of growth often leads to the formulation of theories, which, on mature consideration, appear to have their foundation not so much on facts, as in the wish to discover harmony and logic in all phenomena of life. It is refreshing, therefore, to see a book such as the present collection of six essays by Prof. Bodenheimer, who sets out to discuss without prejudice several of the outstanding problems of animal ecology.

The first two essays deal with the physiological (or theoretical) longevity and life-history, as compared with the ecological (or actual) processes of life in Nature. Important and new suggestions are made with regard to the methods of studying life-histories against climatic background, but apart from that these two chapters contain little that is of wide general interest.

The third essay, entitled "What really occurs in the *Drosophila* bottle?" deals with modern population studies based on breeding *Drosophila* in a limited space. A long series of original experiments is described, in which the population

counts were based on the numbers of eggs, larvae, pupae and adults. The results show most convincingly that previous conclusions as to the critical density of populations were at least partly fallacious because they were based on counts of adults alone, and that the final contraction of a population which has been ascribed to "self-regulation", is actually due to intoxication of younger stages in the breeding medium. This is a striking example of a very attractive theory destroyed by mere facts.

The chapter on biological equilibrium in Nature presents a well-balanced estimation of the relative value of climatic and biotic factors in the control of animal populations in Nature. The author (who used to be an enthusiastic adherent of the climatic school) is coming to the conclusion that both the climatic and the biological school are right to some extent and in some cases, and that the truth can be reached only by their combined efforts. He has some good words to say for the mathematical method as applied to these studies, but stresses the fact that most of the conclusions reached by it are based on extremely simplified assumptions and cannot be as yet applied to natural phenomena.

The fifth essay deals with the problem of animal community, the very name of which presupposes some definite organization. The author marshals some good evidence to show that there is no

justification for approaching the study of animal communities in the same way in which plant communities are studied. He defines an animal community as only "a combination of (plants and) animals, recurring in an approximately similar composition . . . wherever similar ecological conditions exist within the same zoogeographical territory". Each species "exists within the community on its own right", and animal community is only "a useful empirical and statistical conception". These conclusions are bound to call forth severe criticisms and stormy controversy, since community studies have lately become very popular and have led to an extraordinary multiplication of terms and conceptions which tend to present animal community as an organized unit, even as a super-organism. In this chapter the author incidentally comes into conflict with himself, since in discussing the factors regulating the distribution of a species he stresses the fact that the physiological characteristics of a species are not constant and may vary both in time and in space. In the light of this undoubtedly true statement, his own method of constructing life-cycle tables for any climate on the basis of a few observations (on temperature alone) in a single climate, as presented in the second chapter, appears to be an unjustifiable procedure.

The last essay is a bold attempt to face and to bridge the gap between the genetical and the ecological approach to the problems of adaptation and evolution. The author points out that ecology is a much younger science than genetics,

and its field of action is immensely wide and more varied, so that exact experimentation is practically impossible. "Who will reproach the geneticist for preferring his pure, clear-cut kind of thinking to this chaotic state", says the author, who, however, adds that the superior attitude of the geneticist towards ecology may also be partly ascribed to fear that sooner or later the ecological point of view will have to be admitted into his own field. "When this invasion becomes more and more urgent, he knows that the period of the Olympian mind is over and fears that the consequent revolution of genetics will rob him of the certainty of conceptions and results which are so satisfactory to him to-day." Since "the undisturbed peace of mind of the geneticist is not a final aim of biological research", the author urges geneticists to reconsider their outlook and methods in the light of modern ecological research, which, in its turn, cannot develop successfully without the co-operation of geneticists. This plea for co-operation is long overdue, and one hopes that it will, at least, lead to a discussion which is needed to clear the air.

Taken as a whole, the book deserves to be read by every biologist, and it is regrettable that its style is anything but an easy one, while the editors should have been much more drastic in the matter of the English, which is generally very peculiar and at times difficult to comprehend. The system of numbering separately the references to each chapter makes their use very inconvenient.

B. P. UVABOV.

The Flora of South Africa

The Vegetation of South Africa

By Prof. R. S. Adamson. (Monographs of British Empire Vegetation.) Pp. xvi + 235 + 9 plates. (London: British Empire Vegetation Committee, 1938.) 10s.

IN compiling this account of the vegetation of South Africa, Prof. Adamson has had the advantage of a very considerable amount of pioneer work, beginning with the celebrated account by Drège ("Zwei pflanzen geographische Documente": 1843), by Bolus ("Sketch of the Floral Regions of South Africa": 1905), and more recently several papers by Pole-Evans and others.

Three chapters are taken up with accounts of physiography, climate and weather, and geology and soils, and the actual account of the vegetation does not therefore begin until p. 86.

For the well-known 'Cape bush', 'fynbos',

'south-western vegetation' (Bolus) or 'macchia,' the term 'sclerophyll' is used. It is composed of shrubs with evergreen leaves of small size and hard in texture, which enjoy a winter rainfall of not less than 12 inches. This vegetation, among which the families Proteaceae, Bruniaceae, Restionaceae, and others peculiar to South Africa are very conspicuous, is further subdivided into five parts, and it contains very few plants of use to man. In the drier eastern portions of the area, *Aloe ferox* is very abundant, and the 'renosterbush', *Elytropappus rhinocerotis* Less., represents the most arid kind of sclerophyll.

The forest vegetation, which occupies only 0.3 per cent of the area of the Union, is subdivided into four: (1) temperate forest; (2) warm temperate forest; (3) subtropical forest; and (4) montane forest. Only two of these are of much economic importance. The highest trees of the

temperate forest are *Podocarpus* (up to 150 ft.), whilst another well-known tree of economic value is the 'stinkwood', *Ocotea bullata* (Lauraceae). Cleared forest land in this area is used for plantations of exotic pines, gums, and other trees, and some of these grow so rapidly that their timber is of poor quality.

The subtropical forest is, perhaps, the most picturesque. In this there are palms, *Phoenix reclinata* and *Hyphaene crinita*, besides the striking *Strelitzia augusta*, whilst the trees are festooned by lianes and a few epiphytes. Mangroves occur in the estuaries and lagoons of Natal, but they are not extensive. The soils of this forest are deep and very fertile, and the crops grown are maize, Kaffir corn, sugar, tea and cotton, whilst bananas, pawpaws, mangoes, pineapples and avocado pears are much in evidence.

Certain floral regions of other authors are classed together under the heading 'savanna

vegetation'. This includes temperate savanna, embracing the 'acacia grassland' of Natal, the 'bush veld' which occurs in the northern half of the Transvaal, and the 'low veld' of the north-eastern Transvaal.

Chapters devoted to 'grassland' (high veld) and semi-desert (karoo) follow, and the book ends with a short account of land utilization and natural products, and a most interesting chapter entitled "General Conclusions and Prospects".

Having travelled through all these South African regions, the reviewer desires to offer no criticism of this well-written book other than that the first three chapters might have been much condensed, with fewer meteorological details. The space gained could then have been used for more photographs, of which there are only seventeen, and more detailed descriptions of the regions and the numerous interesting plants inhabiting them, few of which are mentioned. J. H.

Diseases of Trees and Decay of Timber

Forest Pathology

By Prof. John Shaw Boyce. (American Forestry Series.) Pp. x+600. (New York and London: McGraw-Hill Book Co., Inc., 1938.) 30s.

PROF. Boyce's work is a welcome addition to the scanty collection of text-books in English dealing with forest pathology. It is mainly concerned to give an account of the diseases of forest trees in North America which are due to plant parasites, and of the fungi which cause decay and stain of timber. Non-infectious diseases are dealt with in a short and summary manner. The book is written to serve a dual purpose. First, it is designed as a text-book and work of reference for foresters in North America, and secondly as a reference book for specialists. The first is, doubtless, its main purpose. This is reflected in the arrangement of diseases according to the organ of the host affected, instead of according to the classification of the parasites concerned, and in the suppression, so far as possible, of technical, mycological and especially taxonomic descriptions. The second purpose is reflected in the carefully selected lists of literature references appended to each chapter.

The quality of the book is seen in the well-informed and carefully balanced discussions, in the well-produced and adequate illustrations, and in the carefully related references to literature. The discussions always seem sufficient to the importance of the subject, especially when one allows for the limitations imposed by the work

being confined to a single volume of convenient size, and for the fact that they are written for a North American public. The European reader will find that many pathogens occur which are unknown in Europe, that diseases which are of considerable importance to him are but shortly mentioned, and that no mention is made of many purely European parasites. In spite of this, the book is of considerable value to British foresters; indeed, there is no other written in English which, for them, so adequately deals with forest pathology.

Any weakness in this work, as a text-book, is involved in its limited objective, which is mainly to give an account of the development and means of control of individual diseases, decays, and stains, in relation to the organisms which cause them. Such a treatment is most successful in dealing with phenomena in which these organisms are all-important, such as the decay of converted timber, or the diseases which arise owing to obligate parasites, such as the rusts. It is very much less satisfactory in dealing with diseases which begin their development owing to the action of some non-infectious factor. Such factors receive very much less attention than they deserve, for to the practising forester they are often of great importance. The failure to deal adequately with non-infectious factors has also resulted in there being no sufficient discussion of the etiology of disease within the forest community in general. The discussion on the deterioration of forest products, because of its almost purely biotic

origin and relatively simple etiology, is not affected by the method of treatment.

There is every evidence in this book of great care in preparation. This is seen in the accurate use of terms, in the clear and simple style of writing, and in the freedom from mistakes. The matter is presented in a manner relevant to the needs of foresters, who as a rule are laymen in pathology. If this not infrequently results in a collection of interesting information about a fungus which it

would be difficult to identify from the text, recourse can always be had to papers cited. In this way is solved the difficulty of catering both for the forestry student, who must needs learn some pathology for his examination, and for the serious student of the subject, who requires more detailed information. Prof. Boyce is to be congratulated on the successful completion of a difficult task, and English-speaking foresters on the receipt of a book of real value and service.

W. R. DAY.

Chemical Analysis

(1) Gas Analysis

By A. McCulloch. Pp. 166. (London: H. F. and G. Witherby, Ltd., 1938.) 7s. 6d. net.

(2) Micromethods of Quantitative Organic Elementary Analysis

By Prof. Joseph B. Niederl and Victor Niederl. Pp. xvi+271. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1938.) 15s. net.

(3) Tables of Reagents for Inorganic Analysis: First Report of the International Committee on New Analytical Reactions and Reagents of the Union internationale de Chimie. By C. J. van Nieuwenburg, W. Böttger, F. Feigl, A. S. Komarovsky, N. Strafford. Pp. xxiv+409. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1938.) 36 gold marks.

IN these days of extreme specialization, it can scarcely be expected that the basic subject of analytical methods will escape selective treatment. The trend is manifest in the preparation and publication of small text-books in which the methods applicable to the practice of a particular industry are selected: these probably save a good deal of time to workers in the special subjects, and to students taking limited laboratory courses in which the practice, rather than the art, of chemistry is demonstrated.

(1) A good example of such books is that on gas analysis, a subject which is much to the fore both in connexion with fuel technology, the science which is enabling one ton of coal to be burnt where three tons were necessary before its application, and in relation to syntheses from elementary gases in presence of catalysts. It covers the field satisfactorily without going into great detail; the more complex apparatus for analysing mixtures of hydrocarbons is omitted.

(2) Quite another field is the micro-analysis of organic substances which has rendered it possible

for the research worker, particularly in the biochemical field, to make astounding progress with quite small quantities of material. Pregl, in Vienna, made the start in this work; his methods have since been copied, adapted, and improved in many centres. The latest book comes from the New York University in Washington Square, and describes and figures the apparatus required, and how to use it. In large research laboratories it is becoming usual, and, indeed, necessary, to set aside a special room for this purpose staffed by competent assistants, who give their whole time to the work. It is good news to hear that there is about to be such a laboratory at the Imperial College, South Kensington.

(3) A third line of development worthy of emphasis is that of reagents. During the last decade the technique of qualitative analysis has been facilitated by the use of an exceptionally large number of new reagents, many of them organic compounds. The Union Internationale de Chimie has set up a Committee of five to report on new analytical reagents and reactions, on which Mr. N. Strafford, of Manchester, represents Great Britain; the report takes the form of a book largely in tabular form, in three languages, an achievement which is in itself substantial.

There are so many new reagents that teachers are faced with problems regarding their suitability which they lack the time to investigate. The report aims at giving help to this end, and contains full information, with references to all the reagents discovered in the period 1910-36. Some of them bear the indication "recomm."

Such a book was badly needed, and will no doubt find shelf room in every laboratory. It is printed and published in Germany.

It is pleasing to have this result of international co-operation, and it may be hoped that, in future, these congresses will more and more have the effect of getting the chemists of the nations to work together to similar ends.

The Silica Minerals

Quartz Family Minerals

A Handbook for the Mineral Collector. By H. C. Dake, Frank L. Fleener and Ben Hur Wilson. Pp. xvi+304. (New York and London: McGraw-Hill Book Co., Inc., 1938.) 12s. 6d.

IN an age when thousands of books are published annually, covering almost every subject, it seems remarkable that so few have been written to introduce the general reader to the wonder and beauty of the mineral kingdom. In the United States some attempts have recently been made to fill this gap in the literature—an outstanding example being “Getting Acquainted with Minerals” by G. L. English. The present work is of the same persuasive kind, and though limited in its field to the silica minerals, serves also as an introduction to general mineralogy.

Like so many other of the common minerals, quartz possesses properties of the deepest scientific interest and furnishes problems, many of which still remain unsolved. Moreover, since some 60 per cent of the lithosphere consists of silica, a great part of which is in an uncombined state, ample material for first-hand study can be gathered by the collector in almost any part of the world, or can be purchased cheaply from a mineral dealer. “Quartz Family Minerals” opens with an explanation of the importance of quartz and a brief survey of its use in past ages. After two excellent chapters, in which the authors discuss the various conditions which led to the deposition of silica minerals in the rocks; a description is given of the quartz crystal habit and of the various types of quartz—crystalline, crypto-crystalline and amorphous.

There is a long chapter on agate; theories of

the manner of its growth are discussed and prescriptions given for producing banded, agate-like precipitates in suitable gelatin media on the Liesegang ring principle. Chapters on opal and on petrified forests complete the descriptive part of the book.

Naturally enough, in a work intended for American readers, the localities quoted for each variety of mineral are preponderantly American. Thus in the section on sand-filled calcites no mention is made of the curious sand-calcite rhombohedra found at Fontainebleau, so well known to the European mineralogist. The beautiful Mexican ‘water opal’ is not described, and quartz cat’s-eye is dismissed in a single short sentence. The last twenty pages of the book deal with “The Art of Cutting Gem Quartz”. In an appendix is given a selected bibliography of books and articles on the silica minerals and precious stones generally, in which the standard British work, G. F. Herbert Smith’s “Gemstones” and Liesegang’s classic, “Die Achate”, should have been included.

Numerous misprints, and one or two factual errors, will need correction in future editions. On p. 36 it is stated that “the purest quartz (rock crystal) has a specific gravity of 2.69” whereas the correct figure is 2.654; and on p. 176 fused quartz imitations of amethyst, etc. are said to have the “identical hardness and specific gravity” of the natural gem, which is by no means true.

Much interesting material, gathered from widely scattered sources, is collected together in the book, and it is well illustrated; it can be read with profit not only by the beginner but also by the more advanced mineralogist. B. W. A.

Applications of Ultrasonics

Ultrasonics and their Scientific and Technical Applications.

By Prof. Dr. Ludwig Bergmann. Translated by Dr. H. Stafford Hatfield. Pp. ix+264. (London: G. Bell and Sons, Ltd., 1938.) 16s. net.

THE scientific study of ultrasonics, or the properties of high-frequency inaudible mechanical vibrations, may be said to date from the year 1883, when Galton published his book “Enquiries into Human Faculty”. In this book he described the construction of the Galton whistle, an

instrument which, refined in some details, is used to this day by psychologists and physiologists for the production of sounds of high pitch. The subject remained of little more than academic interest until, during the Great War, Langevin devised the first practical apparatus for the transmission and reception under water of inaudible ‘sound’ signals. For this purpose, Langevin utilized (1) the discovery by the brothers J. and P. Curie of the piezo-electric properties of quartz, and (2) the methods of generating and detecting electric oscillations made possible by the invention of

the three-electrode thermionic valve. Langevin saw quite clearly that the use of disturbances of short wave-length enabled him to exploit the effects of unidirectional propagation, reflection, refraction, interference, diffraction, etc., until then more usually associated with optical phenomena. He might justly be called the 'Father' of modern ultrasonics.

Soon after the end of the War, Cady showed that the piezo-electric property of quartz could be used to maintain and control the electric oscillations in a suitably designed valve-amplifier circuit. A little later, Pierce and the late J. H. Vincent independently developed similar oscillators based upon the magnetostrictive properties of iron and nickel and their alloys. Almost all the latest developments of ultrasonics have been concerned with the applications of these two methods of producing high-frequency vibrations to various problems of science and industry. Mention may be made of submarine signalling, echo sounding, the sterilization of milk, the preparation of photographic emulsions, television scanning and precision time-keepers. A considerable impetus was given to such investigations by the publications in 1927 of R. W. Wood and Loomis on the physical and

biological effects of high-frequency sound waves of great intensity. These investigators showed how large amounts of energy could in this form be communicated to small portions of matter, with the result that surprising mechanical, thermal, chemical and biological effects were observed.

Until the publication of this book, no comparable comprehensive account existed in the English language of the achievements of ultrasonics and the present state of development of the subject.

Dr. Bergmann's book supplies the need of the moment in a most happy manner, and we have nothing but praise for it.

Particularly valuable is the discussion of the optical methods of measurement and investigation given in chapters ii and iv. The English edition of 1938 differs from the original German one of 1937 by the inclusion of an account of the application of ultrasonics to television, and a list of references to papers published in the interval.

The book is well printed and well illustrated, and shows little evidence that it is a translation and not an original version. We heartily commend it to all who are interested in any branch of this fascinating subject.

F. L. HOPWOOD.

Radioactivity, New and Old

A Manual of Radioactivity

By George Hevesy and F. A. Paneth. Second edition, completely revised and enlarged. Translated by Robert W. Lawson. Pp. xvi+306+5 plates. (London: Oxford University Press, 1938.) 17s. 6d. net.

THIS book was published originally in German in 1923, then in English in 1926 (reviewed in *NATURE*, 118, 475; 1926), again in German in 1931 (reviewed in *NATURE*, 129, 560; 1932), and now appears a second time in English. This new edition has come out at a most appropriate time. It is the only book of its size and scope that includes the great discoveries that have been made in the subject since 1932, discoveries which in fact and interest have exceeded the wildest dreams of the most sanguine workers of ten years ago. They have so enriched and enlarged the subject of radioactivity that the earlier treatises published before 1932, excellent as they were when they appeared, are, if still readable, greatly shorn of interest.

The discovery seven years ago that nuclei of light atoms could be changed by artificially accelerated protons shattered the old view that that kind of thing could be done only by the

spontaneously ejected α -particles from rare and costly elements. Then came heavy hydrogen and the neutron. These had scarcely been discovered before it was found they were excellent projectiles against nuclear targets, and the neutron, in particular, whether slow or fast, has proved so effective against almost every atomic nucleus bombarded that the profusion and variety of the results have become an embarrassment to the compiler.

All this was, in a sense, an extension of Rutherford's original work on artificial disintegration by bombardment, but in 1933 something quite novel forced itself on the attention of experimenters: the production from atoms, radioactive or not, of unstable nuclei which themselves were radioactive, emitting either the β -particle of natural radioactivity or a new particle, the positive electron, which a year earlier had been found in the cosmic radiation. One result of this advance was the extension of the list of elements at the heavy end; radioactive isotopes of the new elements 93, 94, 95, 96 have been prepared by bombardment of uranium and have given the chemist some idea of the chemical character of *eka-rhenium*, *eka-osmium*, *eka-iridium*, and so on.

In this new edition, concise accounts of this recent work have been embodied in the fuller descriptions of the older and fundamental experiments and theories. The book is not overloaded with the new material. It still retains its characteristics as a text-book for the ordinary student of physics and chemistry. The new chemistry (the production of one kind of element by bombardment from another)

and the new artificial radioactivity are admirably related to the old pre-1932 radioactivity which derived from the disintegration theory of 1902-3. Here in three hundred pages, as nowhere else in English, the student is given an account of a great subject in all its important physical, chemical, geological and biological aspects. It is a pleasure to welcome this new edition.

A. S. R.

Vectors

An Introduction to Vector Analysis

For Physicists and Engineers. By Dr. B. Hague. (Methuen's Monographs on Physical Subjects.) Pp. viii+118. (London: Methuen and Co., Ltd., 1939.) 3s. net.

"**V**ECTOR analysis is the natural means of expression for the three-dimensional problems of physics and engineering; because its conciseness and freedom from mathematical detail enable the relationships between the various physical quantities to be kept clearly in view". This is the first sentence in the preface of the book under review. The author continues: "... it has now become almost essential for any advanced worker in these sciences to have some knowledge of vector analysis. Much good work can be done with the aid of a very few elementary principles. It is the object of this monograph to give an introduction to these principles and to explain them from a physical standpoint, so that they may be easily available to the busy physicist or engineer approaching the subject for the first time. Such workers are usually so much occupied by their major task as to lack the time necessary to enable them to seek out such principles as they need to use from the more comprehensive treatises which aim at mathematical completeness. This monograph is not, therefore, intended for the readers with purely mathematical interests, whose more rigorous and systematic requirements are fully satisfied elsewhere. For these reasons the outlook adopted is almost entirely physical; geometrical matters and questions of an exclusively mathematical interest are limited to essentials. Formal proofs of invariance and conditions of continuity in vector processes are replaced by an appeal to physical intuition. Purely analytical topics of an advanced kind, such as Green's theorem, are justifiably omitted from such an introductory treatment as this monograph aims to present. . . ."

The author later directs the attention of the reader to "the inclusion of a chapter giving a

brief sketch of the elementary properties of tensors and dyadics in their relation to vectors. This is a subject which usually puzzles and often repels physics and engineering students because of the abstract mathematical way in which it is usually brought to their notice".

Finally the author informs his readers that "The monograph is based on a course of lectures given a few years ago to post-graduate electrical engineering students in the Polytechnic Institute of Brooklyn, New York".

I have quoted at this length from the preface because I feel strongly that the author has done a valuable service to students and teachers of applied mathematics in producing this small but comprehensive account of vector (and even the elements of tensor) analysis. The publishers also deserve praise for making available at so modest a price a book of 118 pages, including much mathematical printing and 39 diagrams (mostly excellent). In thus commending the book and those to whom we owe its production, I am not endorsing all its contents; there are many things in it that I think might better be put differently (and at no greater length), and a few that seem misleading; but all these points can be dealt with by teachers who may commend the book to their students, as I shall to mine; and readers who study the book by themselves can gain so much knowledge thereby, well set forth in small compass, as will far outweigh the few deficiencies of the treatment.

It is a remarkable sign of the ever-widening vogue of vector methods that this book has been written by an engineer. It is also remarkable that these methods have taken so long in winning adoption, still far from universal. The author points out that even Maxwell, who introduced the fundamental vector ideas into the theory of the electric and magnetic fields, did not make any use of vector analysis in manipulating his equations, relying entirely upon the usual lengthy Cartesian methods. The pioneers of vector methods in applied mathematics were Gibbs, Heaviside and

Lorentz. I recall that my own teacher, Horace Lamb, whose lectures and books were first-rate, never appreciated vector methods; he regarded vectors merely as a means of concise expression (in his view a rather dangerous conciseness), and had no conception of their value in mathematical manipulation.

Dr. Hague's book is already so full of excellent matter that examples on which the reader may

practice his 'prentice hand in vector manipulation are not included and could not be expected, nor is guidance given as to how such skill can be acquired and used, beyond references to further reading on vectors. His inclusion of a brief chapter on tensors and dyads will, it is to be hoped, interest many readers in this fascinating branch of mathematics.

S. CHAPMAN.

Courses in Engineering Science

(1) Mechanical Engineering Science

A Second Year Course. By Dr. Arthur Morley and Dr. Edward Hughes. Pp. xiv+260. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1938.) 4s. 6d.

(2) Engineering Science

By H. B. Brown and A. J. Bryant. Vol. 2: Heat and Heat Engines and Electrotechnics. Pp. x+450. (London: Macmillan and Co., Ltd., 1938.) 6s.

(3) Engineering Mechanics

By Prof. Seibert Fairman and Prof. Chester S. Cutshall. Pp. xi+267. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1938.) 13s. 6d. net.

IT is of interest to observe the variety of views which are current as to the way in which the science of engineering is to be taught, more especially as they are indicated in the text-books of the day. While engineering is, in one sense, merely a branch of applied physics, the training of the engineer must necessarily be conducted on lines fundamentally different from those on which the physicist is prepared for his life's work. Prof. Southwell has pointed out that the problems of the engineer are inexorable and are recognized by him as so. The physicist, barred from progress in one attempted path, is free to try another; the engineer must solve his problem as it is presented, and some solution he must have even though it may only be approximate. From this it clearly follows that the engineer must study his subjects from the practical point of view; and that he inclines not to draw fine distinctions between them but rather to regard them as parts of one whole. Such distinctions as are made are more for convenience than otherwise, and to him the main end is to be able to estimate the practical effect of all the influences which bear upon any work in hand.

Up to about twenty-five years ago, the general practice in technical institutes in Great Britain was to provide a course consisting of quite a number of subjects, each dealt with in a separate

class, with clear-cut distinctions between them. Since then, a tendency has been noticeable towards grouping these individual subjects in more general courses under some such comprehensive title as 'engineering science'. This, no doubt, makes a more attractive-looking subject to the less keen type of student, and it also recognizes in some measure the essentials in an engineering training.

(1) An example of this is the course suggested for National Certificate students by Dr. A. Morley and Dr. E. Hughes. In their text-book "Elementary Engineering Science", the work of the first year in statics, heat and electrical technology was set out. They have now followed this with a second-year course for students of mechanical and of electrical engineering in a more recent text-book, "Mechanical Engineering Science", in which are presented dynamics, energy, hydraulics, and the mechanics of gases, leading up to the principle of the heat engine and a descriptive and explanatory section on engines and boilers.

As in the earlier course, emphasis has been laid on energy as the principal method of approach to the problems which these sections present, and the subject is demonstrated largely by means of practical examples fully worked out. It is in this respect that the book attains its highest qualities, for these examples have been well chosen and are methodically elaborated, no essential step being omitted. The explanatory text might, however, have been arranged in much more simple and direct terms and so have had more appeal to the ordinary student. For example, a straightforward statement of the engineer's point of view as to inertia, mass and weight would have been better than the postulation of different aspects which are not fully discussed and indeed cannot be. Thus they leave the student in some measure of doubt and hesitancy.

(2) A somewhat different sequence has been adopted in "Engineering Science", by Brown and Bryant, the first volume of which presented a first-year course in applied mechanics and hydraulics.

The second volume now shows the work of the second year to be devoted to heat, heat engines and electrotechnics. The scope is thus kept within somewhat narrower bounds, but the treatment goes deeper and, being direct and practical, should make an appeal to both students and their teachers.

The main principles have been stated clearly and succinctly, and the approach to the subject is largely by experiment and deduction. The course outlined is a progressive one and provides a good preparation and basis for the more specialized studies which have to follow, and the student will get considerable help from the numerous illustrations of machinery and apparatus which have been supplied by their makers.

(3) In the preparation of "Engineering Mechanics" by Fairman and Cutshall, the authors have adopted quite a different method of overcoming the difficulty of keeping within the available facilities for study. Appreciating that in institutions

where time is limited by the requirements of other subjects in the curriculum a full basic course cannot be attempted, they have eliminated those portions which must, in any event, be dealt with in more specialized classes and may therefore be deferred until later. They hold that a task is more easily accomplished if all the tools are available, and therefore, at each stage, make careful preparation for it by setting out and explaining clearly the methods, conditions, and the fundamental laws of physics applicable.

The course is one of general mechanics as applied to engineering, and includes statics, dynamics, friction, energy, balancing, impulse, impact and gyroscopic action. It is intended for students who have had a training in mathematics up to the integral calculus, and for such as have this preparation it offers a clearly stated exposition of the subject with a discreet mixture of problems of the practical and the academic types.

Modes of Thought

Modes of Thought

By Prof. Alfred North Whitehead. Pp. x + 241. (Cambridge: At the University Press, 1938.) 7s. 6d. net.

PROF. A. N. WHITEHEAD'S latest book consists of eight lectures and a short address as epilogue. Two of the lectures have been published before under the title "Nature and Life". Any reader who is unfamiliar with the author's philosophy would be well advised to begin with the first of these (Lecture VII). Prof. Whitehead points out there that according to the traditional doctrine of science, which has been taken over by common sense, Nature consists of permanent things, bits of matter, moving about in a space which is otherwise empty. The connexions between such bits of matter are purely spatial, and therefore motion is the only mode of change. Modern physical theory contradicts everything this doctrine asserts, nevertheless it remains as a general presupposition.

The result is a complete muddle in thought, yet any theory which does not presuppose the traditional view seems paradoxical. The traditional view, it is argued, is not merely inconvenient, but definitely self-contradictory. The only final real fact admitted by it is "this bit of matter occupying this region of space at this durationless instant", without reference to any other instant or any other piece of matter or to any other part of space. But what are we to make of velocity, acceleration or momentum at an instant? These notions are

necessary for physics, and yet are without meaning on the traditional view. For the modern view, process, activity and change must be taken as primary matter of fact. At an instant there is nothing. Each instant is only a way of grouping matters of fact by taking a cross-section through them. All interrelations of matters of fact must involve transition. Each concrete fact is the consequence of a process of 'concrecence' from other facts. In its turn it gives way to contribute to the concrecence of others. A thing becomes real by being involved in the "creative advance of nature". The notion of creative advance is the starting-point of Prof. Whitehead's theory.

The rest of the book is concerned with the development of certain aspects of this fundamental notion. The treatment is useful and illuminating for anyone who already knows something of his views. To anyone not so prepared a good deal of it may be puzzling. The author's mode of expression, though often most happy and usually clear, is sometimes elusive. Unfortunately the opening pages are of this character, and might frighten off an unwary reader.

It is interesting and cheering to find Prof. Whitehead, who cannot be accused of ignorance of mathematical logic, combating the fashionable doctrine that arithmetical propositions are all tautological. The doctrine has been propagated with the help of such a terrifying array of technicalities that scarcely anyone has dared to protest against it.

A. D. RITCHIE.

SHORT NOTICES

Anthropology and Archaeology

The Southern Bantu

By L. Marquard and T. G. Standing. Pp. vii+262. (London, New York and Toronto: Oxford University Press, 1939.) 7s. 6d. net.

THE aim of the authors, it is stated, is to remove some of the hindrances to understanding which subsist between the white race and the black. Few who have set out with the same unimpeachable purpose have come nearer success than they do in the few pages of introduction, in which they show how differences in manners and etiquette as between the two races, matters of long tradition, lead to mutual misinterpretation, misunderstanding, or disapprobation. For example, the Bantu is stigmatized as 'furtive' because his etiquette eschews the direct glance, which the European, rightly or wrongly, interprets as a mark of honesty; and this is only one of a number of points, ostensibly trivial, but important in this connexion and cumulative in effect, which give rise to lack of ease in intercourse, or even friction.

From this excellent and sympathetic beginning, the authors conduct the reader through a rapid but adequate survey of the history, social organization, material culture and beliefs of the Bantu of the Union of South Africa, Southern Rhodesia, the Protectorates, and the Mandated Territory of South-West Africa. Full emphasis is laid on the fact, often overlooked in discussion and controversy, that these peoples vary widely in characteristics and culture, notwithstanding a general resemblance. Following on this survey, which will give the reader who is not a specialist in the anthropology of southern Africa an adequate idea of the material with which the native problem, so-called, is concerned, the authors pass on to the conditions of the life of the native as he lives it in the reserves, on European farms, or in European towns, and then set out the circumstances of administration of native affairs, economics, industry and occupation, land tenure, religion, education and the like.

Treatment of the material throughout is objective, and the authors, beyond stating opinions which are generally accepted, refrain from drawing conclusions from the facts. This is left to the reader.

The Origins of Early Semitic Ritual

By Prof. S. H. Hooke. (The Schweich Lectures of the British Academy, 1935.) Pp. xi+74+3 plates. (London: Oxford University Press, 1938.) 6s. net.

THE more intensively the material brought to light in the archaeological excavation of the Syrian site of Ras Shamra, the more clearly is its importance realized in relation to the study of the culture of western Asia in the second millennium B.C. It is the source upon which Prof. Hooke relies

mainly for his most illuminating material in his study of the origins of Semitic religion, which formed the subject-matter of his Schweich Lectures before the British Academy in 1935. His purpose was to relate the ritual practices of the Hebrews, as contained in the Old Testament, to the rituals of Mesopotamia and Canaan. This is now possible, but only through the information which has been amassed in the excavations of archaeologists in the Near East of recent years. As the author points out, such elements of Hebrew culture as the Passover can now be related to the ritual practices, which existed in their ancient Semitic environment.

The first lecture is devoted to the sources and types of Mesopotamian ritual, material familiar to the archaeologists, but as Prof. Hooke suggests, not equally well known to students of the Bible; the second deals in like manner with the ritual of Canaan. It is in connexion with the latter that the material from Ras Shamra is most valuable, for we now have for the first time a contemporary account of Canaanite practice at a crucial moment, hitherto known only from much later and more biased sources. The third lecture brings the Hebrew ritual into relation with the two systems previously discussed, the process suggesting the possible importance for Hebrew culture of Hittite and Hurian influence.

Witchcraft in the Star Chamber

By O. L'Estrange Ewen. Pp. 68. (London: The Author, 103 Gower Street, W.C.1, 1938.) 3s. 6d.

MR. EWEN, whose two earlier books on witch trials drew mainly on the records of the assizes, has now extended his researches to cases before the Star Chamber in the early years of the seventeenth century, not long before its abolition in the reign of Charles I. This court was a convenient and inexpensive method, for the less wealthy members of the community, of seeking redress in a civil action. Its records of trials afford an interesting and in certain respects an enlightening view of the reactions of persons accused of witchcraft. For the cases which came before the court were not witch trials—these went to the assizes—but actions for slander or libel brought by the alleged witch, usually after acquittal in another court, claiming damages from the accuser.

The statements of claims give some interesting information as to the character of the alleged bewitching; but while in some instances there is evidence of a genuine belief in the powers of the witch, not infrequently it is clear that behind the accusation lay the real motive—a family feud, a squabble between the wives of tradesmen, jealousy, or a dispute over property. An accusation of witchcraft would secure removal of an enemy or rival by incarceration for a time at least, and even if unsuccessful left a stigma, which carried with it social

ostracism and even danger of assault by the mob. One of the most interesting cases comes from Berkshire—demoniac possession of a girl of fourteen, a clear case of hysteria, which was investigated personally by King James I, who was a great demonologist; while in another from Oxford the motive of accusation was evidently blackmail.

Biology

German-English Botanical Terminology (Englisch-Deutsche Botanische Terminologie)

An Introduction to German and English Terms used in Botany, including Plant Physiology, Ecology, Genetics and Plant Pathology. By Dr. Helen Ashby, Prof. Eric Ashby, Dr. Harald Richter and Dr. Johannes Bärner. Pp. xi+195. (London: Thomas Murby and Co., 1938.) 10s. net.

ON its publication by Messrs. Murby and Co., "German-English Geological Terminology" received such unanimous approval that the publishers have decided to issue "Terminologies" in other sciences along similar lines. The decision is a happy one, for the series is being written on novel lines.

This book deals with botanical terminology, and the editor of the series clearly made a wise choice in his British and German authors. The book will form excellent material for the student of botany who is learning technical German, for, instead of being a mere vocabulary of German-English terms, it is actually a survey of botany given in English on alternate pages with the German equivalent on the opposite pages.

The subject-matter is divided into: two chapters on plant morphology, two on classification and phylogeny, one on cytology and genetics, one on plant physiology, one on ecology and one on plant pathology. In appendixes are given lists of common European plants, common names of plant diseases, abbreviations frequently used in German botanical literature, and abbreviations used in English botanical literature.

The whole method of approach is commendable, since the book will help the student to enlarge his vocabulary and become familiar with botanical terms in German and English almost subconsciously while reading and revising his botany. Above all, the reader will have impressed upon him the very important fact that the same idea is often expressed differently in German and in English.

We would strongly recommend every student of botany reading for a university degree in the subject to obtain a copy of this very useful work.

Ascaris: the Biologist's Story of Life

By Dr. Richard Goldschmidt. Pp. viii + 312. (London: English Universities Press, Ltd., 1938.) 10s. 6d. net.

DR. R. GOLDSCHMIDT has written this book in order to provide an introduction to biology for readers with no previous knowledge of science. Taking as his unconventional starting-point the parasitic worm *Ascaris*, he uses it as a text for a

very readable account of modern conceptions of physiology, experimental morphology, and genetics, with excursions into bionomics and ecology. In all these matters it need scarcely be said that the distinguished author is a trustworthy guide, and from his point of view the survey is doubtless a well-balanced one.

From another angle, however, the perspective would be very different. Dr. Goldschmidt writes as a convinced mutationist. Mutations arise with "no relation to usefulness or non-usefulness"; natural selection is merely the elimination of the grossly unfit; inheritance of impressed modifications does not happen; organisms having acquired new characters can "afford to look for new modes of living" but otherwise adaptation is an unsolved and perhaps insoluble mystery. It is true that he does not, like some modern biologists, expressly disclaim all curiosity as to evolution. The account of the vertebrate ear leads him on a brief excursion into comparative morphology and even phylogeny and 'recapitulation', although palaeontology is barely glanced at. Nevertheless, with the reservation that there is a great deal more to be said on all these points, the book is one to be recommended to the university student as well as to the layman or the "not-too-tired" business man mentioned in the preface.

Actual mistakes are few and trivial; but surely "the Kerguelas" is scarcely a happy designation for the islands discovered by and named after Yves Joseph de Kerguelen Trémarec. W. T. C.

Chemistry

The Chemical Studies of P. J. Macquer

By Dr. L. J. M. Coleby. (History of Science Library.) Pp. 132. (London: George Allen and Unwin, Ltd., 1938.) 6s. net.

ONE of the outstanding French chemists of the eighteenth century was Pierre Joseph Macquer (1718-1784). He was the author of a dictionary of chemistry which went into a second edition and was translated into English as well as other languages, and in addition to valuable investigations in pure chemistry he was director of the dyeing industries and superintendent of the State factory at Sèvres for the manufacture of porcelain. Mr. Coleby has given a clear and interesting account of the work of Macquer which is based on the original sources, and his book is a useful contribution to the history of chemistry.

The Elements of Physical Chemistry

By F. W. Goddard and Dr. E. J. F. James. Pp. viii+251. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1938.) 5s.

THIS text-book is planned to meet the requirements of students preparing for Higher Certificate, First Medical, and University Entrance Scholarship examinations. The text is clearly written and on the whole very suitable in standard for the aim of the book. The section on atomic

structure requires correction, since it assumes that the atomic nucleus contains electrons, and it is doubtful whether the circular diagrams of atoms are the most suitable for explanations of valency. It is questionable whether adsorption should be introduced into the section on solutions. The sections on solutions and electrolysis are very good, and give an adequate account of the subjects; that on catalysis is rather old-fashioned, and the reactions given on p. 213 for the lead chamber reactions would be more accurate if water were introduced into the first.

A good feature of the book is the emphasis laid on numerical calculations, and the excellent series of problems given at the ends of the chapters will be very helpful on this side. The book is one which should prove useful both to junior students and to teachers.

Geography and Travel

Physiography of Eastern United States

By Prof. Nevin M. Fenneman. Pp. xiii+714+7 plates. (London and New York: McGraw-Hill Book Co., Inc., 1938.) 36s.

THE equivalent in Great Britain of the term physiography is geomorphology, and that is the content of this book. It is planned and written on the same lines as the author's volume on the Western United States which was published seven years ago. The area now covered stretches westward across the Mississippi basin to the edge of the High Plains. It is a massive book, full of detail, arranged under the provinces which in America are the generally accepted physical divisions. As a whole these are the divisions of the country accepted by the United States Geological Survey.

The material available to the author was abundant, though of varying value in different provinces. He has tried, and with a large measure of success, to produce something more than a mere compilation of details. There is certainly much purely descriptive matter, but the broad issues of geomorphological evolution are never lost to view. One might, however, wish for a chapter or two of general summary for those who have not time for the fuller treatment. The book is fully documented on every page and has a number of maps.

Northernmost Labrador Mapped from the Air

By Alexander Forbes, with Contributions by O. M. Miller, N. E. Odell and Ernst C. Abbe. (American Geographical Society Special Publication No. 22.) Pp. xx+255. Navigational Notes on the Labrador Coast. By Alexander Forbes. Pp. 26+6 plates. (New York: American Geographical Society, 1938.) 4 dollars.

THE greater part of this book contains accounts of aerial surveys made in Northern Labrador in the summers of 1931, 1932 and 1935. Previous maps of that part of Labrador were vague and generalized on the whole, although some of the inlets had been charted. Details of the organization, equipment and methods are given with much general information about the country. The methods are fully described by

Mr. O. M. Miller. The net result was a map of some 4,000 square miles extending from Nachvak fjord to Cape Chidley, most of which is produced on a scale of 1:100,000. The sheets accompany the monograph in a separate cover. In addition to this side of the work the volume contains a number of other useful articles, including one by Mr. N. E. Odell on the geology and physiography, and another by Mr. E. C. Abbe on phytogeographical observations, and a separate pamphlet of Navigational Notes on the Labrador Coast by Mr. A. Forbes. The flora of the higher mountains contains many of the same species as the nunataks of Greenland. These Dr. Abbe regards as the hardiest members of the flora, but he does not believe that they survived through the last glaciation on nunataks, which Mr. Odell in any case does not think existed. He favours the hypothesis of relatively rapid migration northward in a past glacial optimum. Subsequent refrigeration may have resulted in a shrinking of the distributional areas of these species.

The volume contains a large number of fine photographs illustrating every aspect of the work.

The South

Its Economic-Geographic Development. By A. E. Parkins. Pp. ix+528. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1938.) 25s. net.

THE title of this book refers to the sixteen States in the south-east of America from Delaware and Maryland westward to Oklahoma and Texas. This area covers a great deal more than the plains of the south-east and the cotton belt since it embraces much of the Appalachian uplands, but is nevertheless a fairly well-defined region on economic and cultural grounds. Mr. Parkins attempts to give a survey of this area leading from physical factors and historical records to the present geographical and economic conditions. In short, he is concerned with an interpretation of life as it exists to-day, in a region that is primarily agricultural but in which agriculture is changing in aspect and intensity and where mining and manufactures are beginning to play an important part. The book, which is well documented and has abundant maps and illustrations, is a valuable contribution to the geography of the United States, and is, moreover, a good example of geographical reasoning.

R. N. R. B.

Engineering

Carburettors and Fuel Systems

The Theory, Application, Construction, Fitting, Testing, Tuning and Maintenance of Carburettors and other Fuel Combustion Devices. By Arthur W. Judge. (Motor Manuals: a Series for all Motor Owners and Users, Vol. 2.) Third and revised edition. Pp. 362. (London: Chapman and Hall, Ltd., 1938.) 6s. net.

THIS, the second volume in a series of four motor manuals which have proved very popular, has now reached the stage of being issued in a third

edition. The series has been designed to present in simple and, so far as possible, non-technical terms the essentials of each branch of the subject, so that it might be of practical service to all who are interested in the motor-car. With this aim in view, its principal features have been descriptions and explanations of the construction and operation of the several parts of the car. Theory has only been introduced to a limited extent, and in the present volume a short introduction puts the reader in possession of the main points as to the theory of carburetion, the chemical and thermal properties of fuels, and the process of combustion. Starting from the simplest types of carburettor, the author builds up a picture of the development of this delicate piece of apparatus as further and further improvements were indicated by the need of greater economy and smoother running of the engine. He retains descriptions of older models because they embody important and interesting principles.

Of up-to-date types a large number are illustrated and described, and among the more recent developments dealt with are the various types of British and foreign carburettors having original systems of mixture compensation, automatic air chokes, acceleration pumps, power jets and other special features. The subject is treated very broadly, as, in addition to those for motor-cars and motor-cycles, carburettors for aircraft are also included, so that with the chapters treating of such ancillary matters as air cleaners, fuel feed systems, design of inlet manifolds, vaporization and testing, tuning and trouble tracing, the information given is very complete of its kind. In its extended form it should continue to prove of great help to motorists, repairers and students and to enjoy a full measure of popularity.

Theory of Alternating-Current Machinery

By Alexander S. Langsdorf. (Electrical Engineering Texts.) Pp. xviii+788. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 36s.

THIS large volume is devoted solely to the theory of the steady state of electromagnetic A.C. machinery (thus excluding electronic devices such as mercury arc rectifiers). Questions of design are touched only so far as they form the background from which the theoretical problems arise. The wide field thus available enables the author to adopt a comprehensive and at the same time broad and easily readable treatment. A specially commendable feature of the book is that the usual analysis by means of vector diagram and complex algebra is always preceded by a very full discussion of the physical relations. In this connexion the chapter on asynchronous machines, which can well be read independently of the rest of the book, should be of special interest to students.

Other noteworthy features of the book are: in the introductory part a special chapter on the theory of polyphase current systems which includes an introduction to the method of symmetrical components, in the treatment of the transformer a discussion of the transformer with three windings, and

in the chapter on synchronous machines a simplified presentation of the Doherty-Nickle theory for the calculation of armature reaction in machines with salient poles. The book can be thoroughly recommended.

A. B.

Autographic Indicators for Internal Combustion Engines

By J. Okill. Pp. 88. (London: Edward Arnold and Co., 1938.) 5s. net.

THIS is a subject which has been somewhat neglected and, as a result, connected information regarding the use of indicators on internal combustion engines is not readily obtainable. The author, who designed that most useful instrument, the Okill maximum pressure indicator, has given the matter much study and, in this monograph, presents a range of information and suggestions which should be most acceptable to those who have not had an extensive experience in the manipulation of these instruments. His survey is limited to the combined piston, spring and pencil-lever types, and traces their development from the original instrument devised by Watt about 1790 to the very carefully proportioned and accurate types now made to suit the severe requirements imposed on them by high-speed internal combustion engines. The possibility of inaccuracy and distortion of diagrams arising from piston friction, overheating and mishandling are pointed out and the methods of testing and calibrating the pencil movements are described. Then after dealing with inertia effects, spring vibrations and the correct forms of connectors, operating gears and other details, a number of present-day instruments are described and explained. The book should therefore be a most useful guide to the many engineers who depend on the indicator for periodical information as to how their engines are operating.

Automatic Telephony

By Charles W. Wilman. Second edition, thoroughly revised and reset. Pp. viii+208. (London: The Technical Press, Ltd., 1938.) 10s. 6d. net.

AUTOMATIC or machine switched telephony is a very specialized subject; but the fundamental principles can be easily grasped. Few relevant text-books indicate these principles without confusing the student with circuit complexities; the author does provide a readable introduction both for students who intend to go further in their studies of the subject and for those who have to include an outline in their general study of electrical communication. The extensive study of the subject is not to be recommended to anyone who has not a suitable flair for the peculiar but necessary diagrammatic nomenclature.

One is surprised that the author does not give a technique for studying complicated switching problems; some form of pictorial shorthand is always used by engineers when studying machine switching circuits or devising new ones. There is likewise no complete circuit, such as a complete call through the minimum of a line-switch and selectors, or a director,

so that the student can have the mental exercise of seeing how the elemental functions, each clearly described with circuits, operate in concord and with economy of apparatus. One would have liked more details of some of the other automatic switching systems in use. We are committed to a Strowger-director system in Great Britain, but other systems, such as the rotary, have special advantages, and are, in fact, largely manufactured here for export. The proportion of telephones in Great Britain which are operated by machine switching is high and is increasing, and no student of electrical engineering can be without some knowledge of the basic ideas. There is little scope for young engineers in automatic telephony, but the inherent principles are widely applicable in many other directions, such as remote-metering and control, traffic-lights, and signalling schemes of all descriptions. L. E. C. H.

Mathematics

Solid Mensuration

With Proofs. By Prof. Willis F. Kern and Prof. James R. Bland. Second edition. Pp. vii+172. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1938.) 10s. net.

THIS is practically a new book although a second edition, for not only is it more than twice the size of the original edition, but substantial alterations have also been made in the text by the authors. After an introductory chapter giving suggestions for practical computation and a clear summary of plane mensuration, lines, planes and dihedral angles are dealt with. Then follows a good course on solids of uniform section, pyramids and cones, frusta, prismatoids and the sphere. Later come the theorems of Pappus without proofs and a consideration of polyhedra. Finally, the general prismatoid is discussed and a proof of the prismoidal formula given.

The book is thoroughly well illustrated by clearly drawn figures—a very essential feature for any book on mensuration—and there is an abundance of interesting exercises with a practical bias, including a good set of review problems.

Les géométries

Par Prof. Lucien Godeaux. (Collection Armand Colin: Section de mathématique, No. 206.) Pp. 215. (Paris: Armand Colin, 1937.) 15 francs.

PROF. GODEAUX'S addition to this excellent series of popular monographs, will be found of interest to the general reader and to the specialist. The former will be made familiar with the fundamental concepts of the various types of geometry; and both will learn much about their historical and methodological background. The six chapters of this work deal respectively with elementary geometry, analytical geometry, projective geometry, the principles of geometry, the theory of groups and topology. The mathematical notation used is quite simple, and the book makes easy reading owing to the explanations covering all the difficult intuitions of the geometricalians. T. G.

Medical Studies

Research in Medicine and other Addresses

By Sir Thomas Lewis. Pp. viii+75. (London: H. K. Lewis and Co., Ltd., n.d.) 5s. net.

THIS book contains a collection of addresses delivered by Sir Thomas Lewis on various occasions, including the Harveian Oration on "Clinical Science" to the Royal College of Physicians, London, 1933, and the Huxley Lecture on "Clinical Science within the University", at the University of Birmingham, 1935, and all first published in the *British Medical Journal*.

During the last twenty years, Sir Thomas Lewis has made outstanding contributions to medicine dealing with disorders of the heart and circulation.

In the preface to this volume, Sir Thomas says that in his earlier days, when working upon physiological problems, he came to the belief that the problems daily encountered in hospital wards, despite their complexity, are capable of solution by a similar form of investigation, that is, by the experimental method directly applied to man, and he tells us that he has never wavered in this belief and that all his later experience has confirmed it. Actually, this method in Lewis's hands has yielded rich results. A second motif running through these addresses is the hope that a science of medicine might develop through the freeing of investigators from the necessity of earning a livelihood by practice. At the end of his Huxley Lecture he says: "It is my conclusion that it is largely within the power of our universities to establish the branch of work that studies disease in living people as a science, by removing the obligation to engage in and teach the practical art, and by treating Clinical Science on precisely the same basis as the allied sciences, physiology and pathology, are treated, thus bringing all the work into real harmony".

Sufficient has been said to indicate the content of these addresses, and many will probably agree that Sir Thomas has established his thesis.

The Health of the Nation and Deficiency Diseases

By John Maberly. Pp. xi+118. (London: Baillière, Tindall and Cox, 1938.) 5s.

THE author maintains that the physique of the younger generation has steadily declined during the last twenty years in spite of improvement in hygiene, labour conditions, and provision for unemployment and sickness as well as for clinics for child welfare. He attributes the ill-health which is prevalent among a large section of the people, especially in the form of neurasthenia, to partially deficient diets resulting from the present methods of milling wheat and the making of white bread. According to him, the vitamins B and E, as well as iron, iodine and copper, which are contained in adequate amounts in wheat but are either wholly or very largely confined to the germ and cortical layers of the grain, are excluded in the ordinary white bread. He therefore recommends an absolute

abolition of the practice of removing the germ and cortical layers of the wheat which at present are given to cattle or poultry, and urges that millers should be compelled to supply flour containing all the nutritious elements of the grain.

The last three chapters, which have no obvious connexion with the rest of the work, are devoted to pernicious anæmia, non-pernicious anæmia and glycosuria and diabetes mellitus respectively.

The Medical Press and Circular, 1839-1939

A Hundred Years in the Life of a Medical Journal. By Dr. Robert J. Rowlette. Pp. x+127+10 plates. (London: Medical Press and Circular, 1939.) 10s. 6d.

THE *Medical Press and Circular* was founded in Dublin by Dr. Arthur Jacob in January 1839 under the title of the *Dublin Medical Press*. The medical profession was entirely unorganized at the time of its foundation, and Jacob was one of the first to recognize the need for organization. To mark its centenary (see *NATURE*, Feb. 11, p. 237) Dr. Robert Rowlette, for many years Irish editor, has written this interesting history of the *Journal* and its development, and has woven into his account the medical history of the times.

The *Medical Press* was published in Dublin up to 1866; but in that year it absorbed a London periodical, the *Medical Circular*, founded in 1852 by Dr. James Yearsley, a well-known aural surgeon, and edited by Dr. George Ross during the fourteen years of its existence.

Arthur Jacob was a prominent surgeon in Dublin, and he was the discoverer of the layer of rods and cones in the retina of the eye. He was succeeded as editor by his son, Dr. Archibald Jacob, and the *Journal* then took a close interest in the betterment of the profession employed under the Poor Law system. In the 'nineties, in common with other journals, it pressed for reforms in the Army Medical Services, and in recent years has pursued an editorial policy of providing concise and authoritative articles upon the latest methods of diagnosis and treatment.

Dr. Rowlette's "History" is attractively produced, being printed on cream antique laid paper, and bound in crash canvas with green labels lettered in gold, and is illustrated with ten excellent plates.

Diets for Diabetes

Arranged in Menu Form. By Dr. G. E. Beaumont. Pp. vi+49. (London: J. and A. Churchill, Ltd., 1938.) 2s. net.

IN this short booklet, diets for those suffering from diabetes are presented in menu form, so that the patient need not calculate equivalent food values from tables. Having been informed by his doctor of the amount of carbohydrate, etc., and number of calories appropriate to his condition, the patient may thus select meals suitable for him, and which appeal to his appetite and his taste. First of all, tables are given of the carbohydrate, protein and fat content and calorie value of fruits, vegetables, meats, etc., after which a number of daily menus is set out, each with its dietary constitution and calorific value. The

diets suggested commence with a scanty one of only 178 calories and become progressively more and more generous. The information given should be very useful to the sufferer from diabetes, and will alleviate some of his trials.

Viscosity of the Blood

The Cause and Cure of High Blood Pressure. By Major Vincent Nesfield. Pp. 96. (London: R. Cobden-Sanderson, Ltd., 1938.) 5s. net.

IN this work, which is based on eight years' research, the author maintains that high blood-pressure is due to increased viscosity or thickness of the blood, for the measurement of which he has devised a special instrument or viscometer.

The chief cause of viscosity of the blood is stated to be over-eating and lack of exercise, which account for its rarity in farm labourers, among whom the author had a practice for more than fifteen years, and its frequency among the well-to-do. Treatment of the condition, therefore, should consist in a reduction of diet and in bleeding, which though carried out to excess in the past has been too much neglected at the present day.

Miscellany

Essential Facts about the League of Nations

Ninth edition (revised). Pp. 349+9 plates. (Geneva: League of Nations; London: George Allen and Unwin, Ltd., 1938.) 1s.

THIS admirable but lucid recapitulation of the essential facts about the League of Nations provides an indictment of recent statesmanship which is the more impressive because the book is wholly free from polemics. The bare statement of the achievements of the League, the outline of its contribution to human welfare in many technical fields as well as in the political, make it the more amazing that nationalist policies anywhere should have hampered that continued development and contribution. The immense amount of readable information provided here in pocket form and easy of reference in itself emphasizes the necessity of a return to the League system and the evolution from within its framework of a more perfect structure where required. Only as the principles upon which the League is based are recognized can there be for any nation either the security or the amelioration of economic conditions which in these last few years have been sought increasingly but in vain by very different methods.

Catalogue of Lewis's Medical and Scientific Lending Library

New edition, revised to the end of 1937. Part 1: Authors and Titles. Pp. viii+550. (London: H. K. Lewis and Co., Ltd., 1938.) 16s. net; to Subscribers, 8s.

THIS new edition of Part 1 of the Catalogue of Lewis's Medical and Scientific Lending Library has been revised to the end of 1937. It contains the list of authors and titles, estimated to be some twenty thousand in number, of the works in the

Library. All works of any importance, English, American and foreign (when translated), are to be found in the Library, as well as a number of journals, reports and annual reports and year-books. All those who have used this Library know how useful it is, and the subscription rates are very moderate. Part 2, which gives the classified index of subjects, is in active preparation, and is expected to be ready early this year.

English for Students in Applied Sciences

By Prof. S. A. Harbarger, W. R. Dumble, W. H. Hildreth and Prof. Bert Emsley. Pp. xiii+260. (New York and London: McGraw-Hill Book Co., Inc., 1938.) 12s.

THIS book outlines a course for American science students in the writing of English. It is thoughtfully written and well produced. Though not entirely suitable in structure or detail for students in Great Britain, it should be found stimulating by their teachers. The average science student's technical knowledge of writing falls far short of his technical knowledge of science, and the difficulty of getting results on paper in a lucid way is often a factor which limits his usefulness as a research man. Many productive workers seem unconscious of the need to examine the bases of composition, or consider the vital relation between author and reader.

A course in English directed to making clear the principles underlying the writing of English, and giving an opportunity for practice in drawing up reports and similar documents, should be of much value in the science courses of English universities. Everyone who has to deal with the preparation of manuscripts for the press or with their subsequent abstraction would be grateful if the universities gave the science student a more deliberate training in this matter. In view of the vast annual output of scientific papers, and the endless labour involved in keeping abreast of them, everything possible should be done to make such papers as clear and understandable as the subject allows.

B. S.

The Official Year-Book of the Scientific and Learned Societies of Great Britain and Ireland
With a Record of Publications issued during Session 1937-1938. Compiled from Official Sources. Fifty-fifth Annual Issue. Pp. vii+169. (London: Charles Griffin and Co., Ltd., 1938.) 10s. net.

MESSRS. CHARLES GRIFFIN are to be congratulated on the promptness with which they have issued the 1938 edition of this useful annual. The extent of the volume is about the same as that for 1937, and checking here and there shows that as regards recent changes of address and similar facts it is up to date. The data given include the full names of every society and institution mentioned, its address, officers, conditions of membership and particulars of meetings and publications. Government institutions such as the British Museum, Kew Gardens, Meteorological Office, and so on, are also included. It is worth emphasizing that the volume is "Compiled from Official Sources".

The Roof-Tree

By James Kenward. Pp. xxv+124+26 plates. (London, New York and Toronto: Oxford University Press, 1938.) 8s. 6d. net.

THIS book traces in a popular and entertaining style the structural development of the dwelling-house. The author has followed its growth from the shelter of a tree, through pre-, proto-historic and historic forms to the multicellular erection of modern type, as seen in the rural dwellings of Kent. Although his illustrations are drawn from a single English county, in which his interest centres, the principles exemplified are of general application. He shows how human needs have been met by extension of the primitive structure along lines determined by constructional possibilities and the character of the material available from local resources. As his title indicates, Mr. Kenward deals only with the northern form of European house evolved from a prototype in which the formative element was a wooden structure. His book is written with an infective enthusiasm for craftsmanship and the craftsman.

Chemical Engineering Economics

By Chaplin Tyler. (Chemical Engineering Series.) Second edition. Pp. ix+241. (New York and London: McGraw-Hill Book Co., Inc., 1938.) 18s.

THE economic problems of chemical engineering are those of industry in general, varied only in so far as production is based essentially on change in chemical form. The graduate entering industry is very soon confronted with them, and finds them to be of a different character and wider in their ramifications than those he has studied for his degree. It will come as a boon to many to have these economic questions concisely and clearly set out in book form. The author is qualified by his experience for this task, which he has accomplished in a praiseworthy manner: there can be few chemists who will not profit by reading it, even though it applies to American conditions.

The subject is considered under such headings as organization, project analysis, plant location and design, operation control and cost, cost accounting and sales development, whilst the research aspect is not overlooked. The tendency towards continuous or semi-continuous operation is emphasized, which involves the construction of large unit plants to reduce the cost of direct labour and supervision. As a result the capital investment in a chemical establishment tends to be much higher than in industry generally, and manual skill is becoming less important in every branch.

Colour Photography in Practice

By Dr. D. A. Spencer. Pp. xvi+275. (London: Sir Isaac Pitman and Sons, Ltd., 1938.) 21s. net.

GOOD colour transparencies can now be made on material readily available in most photographic shops. Colour films are frequently shown in the cinemas, and good colour photographs on

paper are obtainable; but except for the first of these the technique is difficult and requires very great resources of knowledge and equipment in order to produce good results with certainty. The commercial use of colour photography for advertising purposes alone has made it worth while to master the difficulties of reproducible technique and to discover the detail of the operation of the principles of colour photography. Success has not been achieved very long, and there are few workers in colour photography who will not be glad to read this book, which reveals so much of the science behind their craft.

Dr. Spencer treats the subject in relation to the existing successful processes of still photography. He omits colour cinematography altogether on account of its complication and the great space which would be needed for its treatment.

The book is divided into four main parts: Part 1 describes general considerations, including the outline of the principles of subtractive and additive colour photography. It contains also a chapter on lighting and another on the use of colour photographs; Part 2 describes in detail the subtractive methods; Part 3 describes, also in detail, additive methods. Finally, Part 4 outlines the accuracy of reproduction attainable, reproduction of colour photographs by modern illustration processes, and aesthetic considerations.

The widely extended commercial application of photography, and to some extent also the resurgence of its popularity as a hobby, have caused the technical classes in various schools to be well attended. The number of entrants for the City and Guilds examinations in photography also is higher than formerly. The need for better text-books is thus very great. The volume under review will probably be regarded for many years as a standard text-book, combining exceptional clarity of exposition with a readable style in a way which is admirable.

Psychology

Psychology in Everyday Life

By Dr. Walter C. Varnum. Pp. xii + 444 + 16 plates. (New York and London: McGraw-Hill Book Co., Inc., 1938.) 15s.

THIS book is designed for non-professional students of psychology. It will also meet the needs of the inquiring layman.

Written in a perfectly clear and simple style, it presents some of the simpler applications of psychological research in the fields of industry, education and mental health. The author is cautious and restrained, and avoids the sensations and loose generalizations one meets in popular books of this type.

One of the chief merits of the book is that it brings home the utility of much so-called academic experimentation in practical problems. The most satisfactory sections are those on the "Psychology of Learning". Following each chapter is a list of about fifty assertions on topics discussed, which the reader

has to accept or reject as a test of his having mastered the contents of the chapter.

The selection of subjects dealt with in a short work of this kind is, on the whole, a judicious one. Although it is full of factual material and a minimum of discussion this book can scarcely be called a text-book of psychology; but is probably an excellent introduction to the subject for the non-technical student.

J. I. COHEN.

Psychology of Music

By Prof. Carl E. Seashore. (McGraw-Hill Publications in Psychology.) Pp. xix + 408. (New York and London: McGraw-Hill Book Co., Inc., 1938.) 24s.

FROM the preface to this book we learn that it is a logical sequel to the author's "Psychology of Musical Talent". His present purpose is "to stimulate and guide the student of music in scientific observation and reasoning about his art. . . . Since the book is written for beginners, no technical description of apparatus or method is given. . . . Certainly, good service is done by every book which teaches the student of music that his perceptions of musical sounds are not mere reproductions of their physical causes; but, faced with graphs of pulsating frequencies and intensities in a melodic line of music, as performed, the serious student will ask questions that are left unanswered by the author's decision to omit these technical descriptions. The physicist will want to know the nature of the response of the recording instruments, and how they were calibrated. The musician will want to know whether the melodic line was unaccompanied; and, if not, how it was related to its musical context. His question is fundamental; for the foundation of the art of music, as we know it, lies in polyphony.

Seventy-five years ago, Helmholtz directed attention to our ignorance of the psychological section of the theory of hearing. The studies reviewed in this book show how much we have still to learn before the whole story can be told. Meanwhile, not all musicians will accept the whole of the author's postulates as axioms. The book contains a lengthy bibliography, including the titles of papers to which the author refers.

LL. S. L.

Intuition

By K. W. Wild. Pp. vii + 240. (Cambridge: At the University Press, 1938.) 10s. 6d. net.

MISS WILD is to be congratulated on a very readable and careful account of intuition. The whole subject is fraught with difficulties and pitfalls, and it is startling to be presented with thirty-one definitions of intuition.

We cannot help but feel that intuition is in some cases the result of pure chance—when it is regarded as "an abnormal method of knowing based neither on the senses nor on deduction and inexplicable as to its working". There is, as the author wisely points out, much room for research, and possibly the final result of the research may be that there is no such thing as intuition, as some writers would like us to believe about instincts.

Forthcoming Books of Science

Agriculture, Horticulture and Forestry

Announcements

PROF. F. G. DONNAN, emeritus professor of chemistry in the University of London, has been elected an honorary member of the Société Philomathique de Paris. This Society was founded in 1788.

THE following have been elected honorary members of the Royal Meteorological Society: Jules Jaumotte, director of the Royal Meteorological Institute of Belgium, Uccle, near Brussels; Prof. Carl-Gustaf Rossby, professor-in-charge of the Meteorological Department, Massachusetts Institute of Technology; Philippe Wehrli, director of the National Meteorological Office of France.

THE Hillebrand Prize for 1938 of the Chemical Society of Washington has been awarded to Raleigh Gilchrist and Edward Wichers, of the U.S. National Bureau of Standards, for their paper entitled "A New System of Analytical Chemistry for the Platinum Metals," presented before the Ninth International Congress of Pure and Applied Chemistry at Madrid.

PROF. EGON RITTER VON SCHWEIDLER, hitherto general secretary, has been made vice-president of the Vienna Academy of Sciences, and Prof. Ernst Spath has succeeded him as general secretary.

A CHAIR of aerology has recently been instituted in the University of Rome and to it will be attached a laboratory for studies and researches in aerology. The first occupant of the chair is Prof. Filippo Eredia, whose address is Istituto di Aerologia, Via Emilio de' Cavalieri, 7 Rome, 108.

DR. BERNARD H. KNIGHT, lecturer in roadmaking in the College of Estate Management, London, has been recently appointed senior research assistant in highway engineering in the University of the Witwatersrand, Johannesburg.

COMPENSATION has recently been made for the use of the University of Bristol botanic garden for building purposes by the provision of another site on the Royal Fort estate. The new garden will be known as the Hiatt Baker Botanic Garden.

THE centenary meeting of the Royal Microscopical Society will be held on October 25-26. Further information will be available later from the Secretary, Royal Microscopical Society.

THE next meeting of the International Society of Cosmobiology will be held during April 9-11 at Mentone. Further information can be obtained from the general secretary, Dr. Maurice Faure, 24 rue Verdi, Nice.

THE Netherlands Congress of Natural Sciences and Medicine will be held at Nymwegen on April 11-13 under the presidency of Prof. G. Holst. Further information can be obtained from the general secretary, Dr. D. Collingh, Regenteslaan, 2, Bussum.

THE eighteenth International Congress of Agriculture will be held in Dresden during June 6-12, when the following subjects, among others, will be discussed: agronomy, crop production, disease, etc.; vines, fruits and special crops; agricultural industries; agricultural research. Further information can be obtained from the general secretary, Dr. F. Sohn, Hafenplatz 4, Berlin, S.W.11.

A PRIZE of £20 and a diploma are awarded annually by the Royal Asiatic Society for an essay, the object being to encourage interest in the history and civilisations of the East among non-Asiatics. It is confined to members of certain universities. Further information concerning subjects for 1939 can be obtained from the Secretary, Royal Asiatic Society, 74 Grosvenor Street, London, W.1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 438.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The 'Failure' of Quantum Theory at Short Ranges and High Energies

IN Dr. Bhabha's letter in *NATURE* of February 18, reference is made to a breakdown of quantum theory at high energies and short intervals. This seems to be widely interpreted as setting a limit to the validity of our present physical conceptions. Some indeed would associate it with a fundamental discontinuity of structure of space and time. I have no occasion to criticize Dr. Bhabha's letter which, so far as it goes, is opposed to the more extreme interpretations. But I venture to suggest that an unnecessary mystery is being made of what is really an elementary point of relativity theory. In short, we know why the present theory has got into difficulties, and we know what must be taken into account if it is to get out of them.

Relativity theory begins with a denial of absolute motion. Every observed velocity dx/dt is a relative velocity of two physical objects. Likewise the ' x ' of which velocity is the time-derivative is a relative displacement of two physical objects. Both objects are connected with the space-time frame in the way pointed out by Heisenberg; namely, they are not locatable as points (or, in four dimensions, world-lines) but have an uncertainty of position and momentum.

Usually dx/dt and x are assigned to one of the objects (here called the object particle), the other being regarded as a reference body. In precise formulae, the reference body must evidently be a particle. The reference particle is then the physical 'origin' from which the observable co-ordinate x of the object particle is measured. Current quantum theory has repeated the pre-relativity mistake of paying insufficient attention to the definition of the physical reference system to which its exact formulae are intended to apply. It enunciates formulae involving x and $\partial/\partial x$, but omits to specify the standard deviation (uncertainty) of position and momentum of the origin from which x is measured. Clearly, the formulae cannot be true for an arbitrary standard deviation; if true at all, they must hold for a particular standard deviation of position ϵ which ought to have been specified. Since there is no explicit reference, the actual value of ϵ must be implicit in the empirical constants (such as $\hbar/mc$) of the quantum formulae.

When two object particles with co-ordinates x_1 and x_2 are considered, the displacement ξ_1 of one relative to the other is observable independently of any origin of co-ordinates, being the original observable called ' x ' in our second paragraph. This must not be confused with the co-ordinate difference $\xi = x_2 - x_1$, which introduces twice over the uncertainty of the physical origin from which x_1 and x_2 are measured. We have (in the notation of the theory of errors)

$$\xi = \xi_1 \pm \epsilon\sqrt{2}.$$

The failure of current theory is due especially to its omission to distinguish the two observables ξ and ξ_1 .

The physical origin has uncertainty both of position and momentum; for if either were zero the other would be infinite, and the physical origin would not approximate to a geometrical origin with a definite world-line. An energy m_0c^2 corresponding to the mean square of the uncertain momentum is therefore associated with the origin. Except in two-body problems (in which one object particle is used as physical origin for the other) the practice is to treat all the object particles symmetrically; the physical origin must then be an additional *virtual* particle, that is, a particle inserted in the system as part of the apparatus of measurement, but not counted among the object particles, and only taken into account as representing the disturbance of the system which the carrying out of a measurement implies. The energy m_0c^2 belongs to the physical origin contemplated as a virtual particle, and gives it a proper mass m_0 . In order that quantum equations may be definite, the uncertainty constants ϵ and m_0 of the physical origin must have standard values.

Naturally physicists who have neglected the uncertainty ϵ of the origin will find that their equations break down at distances of order ϵ . Nothing has gone wrong with space; it is the theorists who have failed to apply their own principles in relating the observable physical system to space. To state their failure summarily: there are two recognized principles of observability, namely, the quantum principle that an observable *object* has an uncertainty relation to the geometrical space-time frame, and the relativity principle that an observable *quantity* relates to two observable objects. Current theory recognizes these principles separately but not in combination; and in dealing with co-ordinates and momenta it pays attention only to the uncertainty at the object-particle end of the relation.

The remedy is obvious. I do not say that the application of the remedy is an easy matter; but, if it is clearly the thing most worth doing, that will not deter anyone. An astronomer, unable to solve his own 'problem of three bodies', can only admire the success with which physicists tackle the more numerous closely interacting particles of the nucleus. But I think the advance would not be less rapid or less substantial if they gave up using the wrong formulae. My own work¹ (chiefly concerned with the momentum uncertainty m_0) has been confined to extra-nuclear problems; no insuperable difficulty has appeared, though progress has not been easy.

I turn now to the actual values of ϵ and m_0 . A geometrical frame of space-time is not a physical reference system, since its exactitude is incompatible with observability. (To assign infinite mass to the frame, so as to make both its position and velocity exact, would introduce infinite curvature, and defeat its use in a different way.) We turn it into a physical

frame by associating with it uncertainty constants, namely, a particular length ϵ and a particular mass m_0 . (In mathematical treatment we should assign to the frame a wave function describing a probability distribution corresponding to these constants.) These 'put the scale into' physical systems, and all other natural lengths and masses will stand in a definite numerical ratio to them. Since we observe only relative scale, the arbitrariness of the initial choice of ϵ and m_0 is eliminated. From extra-nuclear investigations I have found that m_0 is 10/136 of the mass of a hydrogen atom; and ϵ , which is very simply related to certain magnitudes calculated in cosmological theory¹, has the value $1 \cdot 10 \times 10^{-13}$ cm. (For technical reasons, the constant more usually given is $k_0 = 2\epsilon = 2 \cdot 20 \times 10^{-13}$ cm.)

That the virtual particle of mass m_0 , originally studied in extra-nuclear theory, is the particle now used in nuclear theory under the name of 'mesotron', or 'meson', admits, I think, of no doubt. But whether the usual assumption is correct, that nuclear mesotrons are the same as the actual mesotrons observed in a Wilson chamber, I have no means of judging. Since m_0 and ϵ are conjugate, it is optional which we treat as the more fundamental; but I would point out that to proceed *via* the mesotron mass is a roundabout way of getting at the range of nuclear forces, since the range is an immediate manifestation of the uncertainty of position of the origin. The nuclear force between two protons comes from an energy-singularity occurring when two protons coincide—a sink which (in uniform distribution) just compensates the Coulomb energy occurring when they do not coincide. The condition of coincidence $\xi = 0$ gives $\xi_0 = \pm \epsilon/\sqrt{2}$, which (for the calculated value of ϵ) agrees exactly with the range of force found by Breit, Condon and Present in their discussion of the scattering of protons.

Variation of Field Penetration with Temperature in a Superconductor

We have recently completed an investigation of the magnetic threshold fields for thin superconducting films of mercury. The extended magnetic transition curves described in a previous communication¹ have been removed by using in place of a strip of film a circular disk with embedded current and potential leads. In this way, effects due to the diminishing thickness of the film at the edges of a strip are eliminated.

Fig. 1 gives an example of the results obtained. The left-hand scale of ordinates gives the values in gauss of the critical field at half-height at different

temperatures for a film $1 \cdot 2 \times 10^{-4}$ cm. in thickness. The right-hand scale gives the corresponding values of H_f/H_c , where H_f is critical field for the film and H_c is critical field for bulk mercury. To give an idea of the consistency of the results, values for successive films are plotted with different symbols. Values are included for films deposited at various temperatures

Fig. 1.

and afterwards annealed to different degrees. The agreement shows that we are here dealing with a true size-effect independent of structure.

It can be seen that the field-ratio H_f/H_c rises very steeply in the neighbourhood of the transition temperature and that it seems likely to approach infinity at that point. Unfortunately, there is no complete theory of the threshold fields for superconductors of small dimensions, but it is generally accepted that the critical field will increase rapidly when the conductor becomes comparable in thickness with the depth of the field penetration. We conclude from our experimental results that the field penetration is not constant, but that it increases rapidly near the transition point and may even become infinite there.

In default of an explicit formula, we may assume

$$\frac{H_f}{H_c} = f\left(\frac{d}{\lambda(T)}\right),$$

where d is the thickness of the film and $\lambda(T)$ is a parameter (of the dimensions of a length) which defines the field distribution inside the superconductor.

If we now take two films of thicknesses d_0 and d and find two temperatures T_0 and T at which the values of H_f/H_c are the same, we have:

$$\frac{d_0}{\lambda(T_0)} = \frac{d}{\lambda(T)}, \text{ or } \frac{\lambda(T)}{\lambda(T_0)} = \frac{d}{d_0}.$$

In this way, from a series of experimental curves for film thicknesses varying by a factor of 50, we have built up a rough curve giving the relative values of $\lambda(T)$ at different temperatures. Fig. 2 shows a curve so obtained. Ordinates are ratios of field penetration at any temperature to field penetration at 2.5° K. With one or two doubtful exceptions the points fit on a smooth curve.

If we accept a theory of the London¹ type, this result can be most simply explained by assuming that the number of electrons responsible for superconductivity is small or zero at the transition point and increases rapidly as the temperature is lowered. A similar suggestion was advanced by Gorter and Casimir² some years ago to account for the specific heat anomaly at the transition point.

Fig. 2.

○, APPLEYARD, BRISTOW AND LONDON.

×, SHOENBERG'S RESULTS. (See letter below.)

The absolute magnitude of the field penetration can be estimated by making certain reasonable thermodynamic assumptions. With an exponential type of field-distribution, we obtain the relationship

$$\frac{H_f}{H_c} = 1 + \frac{\lambda}{a}$$

for very thick films.

Our results are in agreement with this expression and give a value $\lambda = 1.2 \pm 0.1 \times 10^{-6}$ cm. at 2.5° K., which is of the same order as the rough estimate made by Pontius⁴ using thin wires of lead.

Superconducting Colloidal Mercury

THE magnetic properties of some colloidal mercury preparations have been investigated by a ballistic method, and provide direct evidence for the existence of a small penetration depth of a magnetic field into a superconductor, and for a temperature dependence of this penetration of the same kind as observed by Appleyard, Bristow and London¹. From the initial slope of the magnetization curve, the magnetic

Fig. 1.

moment per unit field per unit volume of mercury (χ) can be deduced for the small spherical particles of the colloid, and this was found to be appreciably smaller numerically than the value $\chi_s = -\frac{1}{3}\pi$ for a large sphere (in which the penetration of the magnetic field is relatively negligible), and to decrease with increasing temperature towards the transition temperature (4.17° K.). This is illustrated in Fig. 1,

Fig. 2.

which shows the temperature variation of χ/χ_0 for a colloid of mercury in gelatine (average particle diameter of order 10^{-6} cm.). From the magnetization curves, the critical field h was also obtained, as the field at which the magnetization disappeared, and as in the case of thin wires² and thin films³, h was larger than the bulk critical field H_c ; the temperature dependence of h/H_c is shown in Fig. 1.

The fact that χ/χ_0 is less than 1 can be immediately interpreted as due to a penetration of the magnetic field into the particles, to a depth comparable to the particle size, while the fact that χ/χ_0 decreases with increasing temperature must mean that this penetration increases. It will be seen that h/H_0 increases just in the region where χ/χ_0 is decreasing, thus confirming the inference of Appleyard, Bristow and London¹ that this increase is associated with an increasing penetration depth. Similar results were obtained with an emulsion of mercury in chalk, but the effects were less pronounced owing to the larger average particle size.

Measurements were also made with a colloid of mercury in albumen in which the particle size was about ten times smaller than for the gelatine colloid, and the values of χ/χ_0 were now extremely small (Fig. 2), showing that the penetration of the field was almost complete. The critical fields, however, were so large that they could not be reached with the largest field used (900 gauss) even at the highest temperature.

If the law of falling-off of magnetic field into the surface of a superconductor is known, the value of χ/χ_0 can be calculated as a function of r/λ , where r is radius of the sphere, and λ the penetration depth. The London theory⁴ assumes the law to be according to the differential equation $\nabla^2 H = H/\lambda^2$, and with this assumption it has been shown⁵ that

$$\chi/\chi_0 = 1 - 3\left(\frac{\lambda}{r}\right) \coth \frac{r}{\lambda} + 3\frac{\lambda^2}{r^2} \quad (1)$$

which for $r \ll \lambda$ reduces to

$$\chi/\chi_0 = \frac{1}{15} r^2/\lambda^2. \quad (2)$$

Assuming this formula, we have calculated λ/λ_0 as a function of temperature for the albumen colloid, and as can be seen from Fig. 2 of Appleyard, Bristow and London's note, the results agree quite well with those from the thin mercury films, suggesting that equation (2) is of the correct form. At present only the order of magnitude of the average value of r^2 is known, so the absolute value of λ_0 cannot be given exactly; it agrees, however, in order of magnitude with the thin film estimate. It will be noticed that close to the transition point, T_0 , χ/χ_0 decreases linearly with $T_0 - T$, which means that the penetration depth becomes infinite at $(T_0 - T)^{-1/2}$.

In the case of the larger particles, as in the gelatine colloid and the chalk emulsion, the London assumption cannot be tested exactly, since the lack of uniformity of particle size complicates the application of equation (1); this complication does not arise in the case of particles so small that equation (2) can be used. It is hoped to overcome this difficulty by working with a more uniform preparation of known particle size.

In conclusion, it is a pleasure to thank Mr. R. T. M. Haines, of British Colloids, Ltd., for preparing the colloids used in these experiments.

Atomic Nuclei in Primary Cosmic Radiation

It is generally assumed that the mesotrons in cosmic radiation are produced by primary electrons in the upper atmosphere, but there seems as yet not to be any direct evidence for such a process. On the contrary, experiments by Jánosy¹ indicate that electrons cannot produce mesotrons with a probability sufficient to account for the intensity of the mesotronic component.

According to a recent theory of the origin of the cosmic rays², these are likely to constitute a more or less fair sample of the charged particles in the neighbourhood of the stars (especially the double stars). This means that the primary cosmic radiation is likely to contain electrons but also a considerable fraction of atomic nuclei with very high energies.

The number of protons or other nuclei observed at sea-level is, however, very small. This might be accounted for by the assumption that incident high-energy nuclei are strongly absorbed when colliding with nuclei in the atmosphere. Such an absorption could be due to a nuclear correspondence to the *Bremsstrahlung*³, which would imply that it is accompanied by the emission of mesotrons. This would explain the origin of the mesotrons in cosmic radiation at the same time. Processes of this kind must be accompanied by nuclear explosions of the kind observed especially at high altitudes. As the frequency of the explosions increases extremely rapidly with the altitude, it is improbable that they are caused by the mesotronic or electronic components.

In order to fit observations, the nuclear absorption cross-sections in air must be at least $\sim 2 \times 10^{-25}$ cm.² which at the energies concerned corresponds to 1.4×10^{-28} cm.² in hydrogen. For the latter, Euler and Heisenberg⁴ give as a preliminary theoretical value $\sim 10^{-28}$ cm.².

Bursting of Glass Tubes by Thixotropic Pastes

In a test for the liquid absorption of light powders, water is gradually added to the powder in a hard-glass thick-walled test-tube fitted with a rubber bung. This is shaken between additions by giving several successive brisk taps each with the closed and the stoppered ends downwards on to a rubber pad until a paste is produced which flows out under certain standard conditions. The tubes, of 155 mm. length and 22 mm. bore, are about half full at the completion of the test.

Occasionally, while tapping the tube stopper downwards, the end of the tube bursts outwards and the main bulk of the paste is violently thrown a considerable distance as a single blob. The pastes are strongly thixotropic (false-bodied) and the bursting occurs at the stage when the paste appears quite fluid during shaking but sets rapidly and will not flow out. On these occasions the operator is not sensible of having used excessive force; indeed,

there is a feeling of surprise that such an effect should be produced by a relatively light action. It is significant also that during tapping a sharp click, resembling the impact of a column of mercury on the end of an evacuated tube, is sometimes heard. This is especially noticed when the paste is shaken down to one end and the tube then inverted and tapped with this end uppermost. This sound cannot be produced with water only in the tube, neither is it possible using reasonable force to burst such a tube containing water.

A singular feature is that in the cases we have noticed the type of fracture is always the same and, as will be observed from the accompanying photograph of four tubes collected in 1938, has a symmetrical character. The first three are Monax and the fourth, on the left, is of combustion quality hard glass. The similarity of fracture reflects the directional properties of the forces acting on the different occasions, and since the tubes are well annealed it is presumed that the axis of symmetry of the fractures is related to the plane in which the tube was moving when it burst. (A recent experience suggests that the two planes are at right angles.)

As a tentative explanation of the bursting, it is suggested that the main body of the paste sets into a piston-like cylinder which slides easily in the tube because it is violently sheared at the surfaces where it becomes fluid—a characteristic of thixotropic pastes. This piston slides downwards on impact and then, absorbing the energy of the blow, rapidly returns as a whole to the upper end. Since the pastes have very high yield values, the piston has considerable strength and is presumably rigid enough to prevent air 'blowing' through it. Thus effectively all the air is confined to the lower end, leaving a vacuum in the upper space, so that the piston on returning to this end impacts violently without the cushioning effect of the air film. Such an impact would be absorbed by the rubber bung, but the rigidity of the glass is such that bursting occurs when the closed end is uppermost.

It would be interesting to design an impact apparatus to test our suggestion as to the importance of the type of paste and to measure the forces involved, but at the moment we have no time to pursue the matter further.

Flavin Component of the Pyruvic Acid Oxidation System

EVIDENCE for the earlier suggested¹ participation of a flavin compound in pyruvic acid oxidation by *Bacterium Delbrückii* has been obtained by a procedure similar to that used by Warburg and Christian² to remove the prosthetic group (flavin-adenin dinucleotide) from amino-acid oxidase. Phosphate extracts derived from the lactic acid bacteria were repeatedly precipitated with 50 per cent ammonium sulphate at pH 3 at 1–2° C. By this treatment a protein fraction was obtained, which on addition of thiamin (vitamin B₁) pyrophosphate only³, did not catalyse pyruvic acid oxidation, but did so on addition of thiamin pyrophosphate together with flavin-adenin dinucleotide, kindly supplied to me by Prof. O. Warburg.

In the following experiment, 1 ml. of protein solution, corresponding with 0.1 gm. of dried bacteria, was shaken with air for 30 minutes at 37° in the presence of 0.1 mol. pyruvate:

Thiamin pyrophosphate	..	—	15γ	15γ
Flavin-adenin dinucleotide	..	20γ	—	20γ
Oxygen used (ml.)	..	15	5	248

Riboflavin and the 'old' yellow enzyme were inactive.

In the light of our hypothesis that thiamin when acting as coenzyme is reduced reversibly⁴, it is not surprising to find the insertion of a flavin compound between the assumed α -dihydrothiazole and oxygen. We know from the work of Warburg, of Karrer and of v. Euler that compounds of this type (for example, the dihydropyridines) are not autoxidizable, but do easily reduce flavin, which in turn is autoxidizable. Also, it seems significant that in the animal cell the same flavin-adenin dinucleotide has been found^{5,6} to be the prosthetic group of diaphorase⁷ (coenzyme factor⁸), the carrier between pyridine coferments and cytochrome.

Present Condition of a Twelve-Year Old Pure Strain of Carcinoma Cells *in vitro*

ON February 23, 1927, five small fragments of a mouse adenocarcinoma (Frankfurt strain of Ehrlich) were cultivated as hanging drop cultures¹. With slight modifications, the culture medium used has remained practically the same throughout this period of twelve years. The medium used for cover-glass cultures consisted of one volume of a plasma mixture (equal parts of chick and rat plasma) and one volume of embryonic tissue juice of chick. For cultures in Carrel flasks, the solid medium was composed of equal parts of dilute chick and rat plasma coagulated by a drop of embryonic tissue juice; the supernatant liquid phase, 0.5 c.c., consists of 20 per cent embryonic tissue juice (chick), 20 per cent rat serum and 60 per cent 'Tyrode' solution.

Research Items

Painted Skulls from Northern Australia

D. F. THOMSON, who was recently engaged in observing conditions among the aborigines of Northern Australia on behalf of the Federal Government, figures and describes in *Man* of January two painted skulls, which were obtained by him in north-east Arnhem Land. The practice, which is found among groups occupying the territory between Cape Stewart on the Arafura Sea and Blue Mud Bay on the Gulf of Carpentaria, is closely bound up with funerary customs and totemic beliefs. The material is transient as the pigment used is mixed with water, and the skulls, after being carried about by a relative, usually a woman, for a period of two or three years, are pulverized with pounding stones. Hence no record is left which might provide a key to further investigation. Great numbers of the painted designs are employed on ceremonial occasions, each group having an appropriate type for painting the bodies at initiation, after death, and later on the skulls, also on grey-bearded men and upon a man some-time after the conclusion of the final ceremony at which he attains the status of full initiation to the totem group. Each group, sometimes bound together by so slender a thread that it can be understood only by study of mythology, owns distinctive patterns. The right to use these is vested in members of the group only and guarded with the most intense jealousy, as it is bound up with the spiritual and social existence of the group. It is believed that the 'marks' were present on the bodies of the ancestors, when they sank beneath the waters at the sacred places marked to-day by water holes, at which the totemic objects are kept, and to which they are returned at the close of the totemic ceremonies. These are also the places from which emerge the shades of the babies when they enter their mother at conception. The significance of the designs is clearly that they are used in rites of aggregation. Hence the painting of the skull is in the nature of a benediction and a consecration.

Statistics of Literary Style

THE science of statistics, originally restricted to problems of the State, has long been extended from demography and economics to biology and psychology, but it is rather surprising to find it applied to problems of literary style and disputed authorship. When the application is made by such an authority as G. Udny Yule and published in *Biometrika* (30, 363; 1938), it cannot be dismissed as a mere curiosity. What Mr. Yule has done is to make an analysis of the sentence-length of certain authors. Thus, for example, Bacon's "Essays" contain three sentences containing 1-5 words, sixteen containing 6-10 words, forty-nine containing 11-15 words, . . . and so on. This forms a frequency distribution, which can be analysed by any of the usual statistical methods. Mr. Yule has selected the mean, median, upper and lower quartiles, interquartile range, and ninth decile. These numbers come out very differently for Bacon, Coleridge, Lamb, and Macaulay. Moreover, if the tests are applied to two fairly long extracts from the same author, on similar subject-matter, they give reasonably consistent results. This seems to show

that sentence-length can be taken as a characteristic of the author's style. As an example of the application of these methods, it is shown that the style of "De Imitatione Christi" is consistent with that of Thomas à Kempis, but not with that of Gerson, to whom the work was sometimes attributed. Similar objections are raised against attributing the authorship of "Observations upon the Bills of Mortality" to Sir William Petty.

Habitat of the Lapwing

THE Edward Grey Institute of Field Ornithology, Oxford, has issued in booklet form a hundred pages of reprints from *British Birds* covering the 1937 lapwing habitat inquiry conducted by E. M. Nicholson with the co-operation of fifty-five observers in twenty-six English and one Welsh counties. It did not appear that different geological formations or soils influence very substantially the distribution of this species (*Vanellus vanellus*), but it was not found breeding freely much above 1,200 ft., and steep slopes are generally avoided. The most frequent habitat types are newly ploughed land, fallow and stubble, and fair permanent pasture above alluvial level. Tidal beach or shore, margins of salt or brackish standing water, bare peat and rabbit warrens are little used, and dry shingle, bracken moorland, bare stony mountain, urban public parks and playing fields, scrub with trees and bushes and woodland clearings were avoided. Farming, burning and flooding cause substantial changes in their haunts. Material collected for nesting shows no apparent preference between a wide range of different habitats; flocks may occur at all seasons but are largest in the second half of the year, feeding or roosting in all weather conditions at all times of the day, resting birds often pecking closely in some hollow or sheltered slope. Heavy passing traffic and farm workers' movements have little effect upon the bird, nor do wild mammals, birds and livestock have much noticeable effect, but some parasitism by gulls was noted. The lapwing is essentially a bird of the soil, it is noted, and therefore closely linked with agriculture. It is stated there is still scope for further study, including intensive survey work on limited areas, study of flocks over large areas, fifty-field samples at different periods, study of daily time-tables for the species, and study of its diet in relation to other factors. There is appended an important ecological survey by M. D. Lister of the lapwing population on a 225-acre Epsom (Surrey) arable farm, showing annual fluctuations and relations to crops.

Division of Labour among Asiatic Ants

THE workers of the Asiatic carpenter ant, *Campenotus japonicus* var. *atrimus*, differ greatly in size, but form a continuous series from smallest to largest, although there are some slight morphological differences among them observable, for example, in the proportions of the head. In a series of field observations, Juishuan Lee has endeavoured to classify the activities of the workers in relation to the size grade of the individuals (*Peking Nat. Hist. Bull.*, 13, 137; 1938). The results show that specialization is much less marked than in some species, for every worker

class was found to share in all kinds of work within the colony. The only difference was that certain activities were performed predominantly by one particular class. Thus large workers took most part in work requiring strength and courage, such as fighting, foraging, guarding and exploring, and also in food regurgitation, which is probably related to foraging. The small workers are most active in carrying, foraging, building, tending the young and carrying the jumping plant-louse. The intermediates are active in all sorts of labours, but always to a moderate extent, neither most active nor most indifferent. Division of labour, therefore, has here no definite specialized castes, but is exhibited as a matter of degree whether expressed in size or in activities.

Response of Leaves to Gravity and Light

LEAVES of terrestrial plants usually tend to orientate themselves so that the upper surface of the lamina is perpendicular to and facing unilateral light. Their reaction to gravity tends to bring the lamina horizontal. The combined stimuli of light, gravity and any others result in a position effecting a compromise. W. Neilson Jones has recently carried out some interesting comparative work on this subject, using the leaves of the terrestrial *Tropaeolum majus* and the floating leaves of *Limnanthemum peltatum* (*Ann. Bot.*, New Series, 2, No. 8, 819; 1938). He found that the leaves of both plants tend to orientate their laminae in relation to gravity by curvatures of the petioles in such a way as to bring the laminae into a horizontal plane. On the other hand, leaves of *Tropaeolum majus* are also sensitive to unilateral illumination, whereas those of *Limnanthemum peltatum* are not. This reaction to light, he claims, may be expected on biological grounds as a general difference between aerial and floating leaves.

Bacterial Reduction of Nitrates

The mechanism of nitrate reduction in *Bacterium coli* (*Escherichia communior*) has been investigated by Syunji Yamagata ("Über die Nitratreduktase von *Bacterium Coli*", *Acta Phytochimica*, 12, No. 2, 283; Oct. 1938). Several research workers have maintained that the reduction of nitrates is accomplished by the usual dehydroase system of the bacteria. The present experiments with cell-free enzyme preparations show, however, that the reduction is accomplished by two separate enzymes, according to the following plan:

The two enzymes are shown to be separate mainly upon their varying reactions with potassium cyanide.

Accuracy of Direction Finders

On March 1, R. L. Smith-Rose, of the National Physical Laboratory, presented a symposium of papers on direction finders to the Wireless Section of the Institution of Electrical Engineers. The first paper on the subject describes an improved medium-wave Adcock direction finder, and was published in 1937 (*J. Inst. Elec. Eng.*, Nov. 1937). Since that date, four papers have been published in the *Journal* and a further one by W. Ross was read at the meeting, all of which discuss direction finders used in wireless.

In the operation of radio-direction-finding, the user is generally faced with the problem of effecting the best possible calibration of his instrument which circumstances permit. Ideally, an overall calibration would be made by setting up a transmitter at known points in the sector and at the distances for which the direction finder is required to be used. Mr. Ross explains how this is not always possible and the expedient of using calibrations made at one particular distance for transmissions from all distances frequently leads to errors. Part at least of the error revealed by calibration, as for example, the error arising from changes in the medium in which or over which propagation takes place is frequently found to vary considerably with distance. That part of the error which arises from the instrument itself is a constant and if known could always be allowed for accurately. If an ideal overall calibration is not possible, it is best, as a rule, to allow for the instrumental calibration only. The errors due to various causes are discussed mathematically and it is shown how the results obtained can be applied practically. In particular, the case of a four-aerial Adcock direction finder is considered at length. The effects of ground attenuation have been neglected, but on very poor sites the radiation component of the electric field from a short vertical radiation will attenuate with distance more rapidly than inversely as the distance, which has generally been assumed throughout the analysis. The papers presented at this meeting should be a great help in increasing the practical accuracy of direction-finding in navigation.

Galactic Rotation

G. L. CAMM has recently issued a paper entitled "A Study of Galactic Rotation, based on the Velocities of the Planetary Nebulae" (*Mon. Not. Roy. Astro. Soc.*, 99, 2; 1938) in which he analyses the radial velocities of the planetary nebulae to discover the relation between the angular speed of rotation of the galaxy and the galactic radius. A knowledge of the distances of the nebulae is essential and the method adopted was to use angular diameters and apparent magnitudes, treating them as equally reliable indicators of distances. The method is admitted to be too crude to make any allowance for interstellar absorption or for the effects of selection; but the author shows that the former is of little consequence. From Table 1 it appears that, though the planetary nebulae are close to the galactic plane, they are affected by interstellar absorption to a very small extent. From the analysis of the radial velocities there are deduced values for the constants of solar motion, the distance and direction of the galactic centre and also a constant K-term. The proper motions of twenty-one planetary nebulae determined by van Maanen were used to find the linear speed of rotation at the distance of the sun; but the result is unsatisfactory owing to the fact that the proper motions are too few. On the assumption of a linear speed of 275 km./sec. at the sun's distance, the variation of the gravitational attraction of the galaxy is shown to be similar to that arising from a thin circular disk, its density decreasing uniformly outwards, and a massive nucleus existing at the centre of the disk. It is interesting to notice that the best agreement between this model and the observed radial velocities of the planetary nebulae is obtained if the mass 0.76×10^{11} is assigned to the nucleus and 1.01×10^{11} to the disk, the mass of the sun being the unit.

British Industries Fair

AS year succeeds year, the visitor to the British Industries Fair, on the lookout for exhibits of scientific interest, finds the range and variety ever greater. Looking back over a period of years, he cannot fail to be struck with the emergence from time to time of entirely new industries, the fruits of scientific research and discovery. Not only so, but also the scope of long-established industries is being continually widened, as new products or new applications of old products are discovered. As one goes through the specifically scientific exhibits or exhibits possessing some scientific interest, one can picture the character and the extent of the prolonged scientific research that must have preceded the eventual production of the materials or articles exhibited.

The chemical industry in particular each year brings before the visitors to the British Industries Fair new products and long-established products manufactured to a still higher degree of purity, to meet modern needs. It may also be remarked that the art of displaying the exhibits seems to improve each year, although the writer noticed in a few cases a tendency, perhaps, to elaborate the framework at the expense of the exhibit framed. On the whole, however, this year marked a distinct advance in what may be called the informative and educative value of the exhibits. For example, this year's main stand of Imperial Chemical Industries, Ltd., at Olympia, consisted of a well-set-out diagrammatic exhibit dealing with the production of ammonia and its varied uses. Displays dealing with water sterilization, the preparation of rubber latex, refrigeration and metal production exhibited the uses of ammonia in its anhydrous form. The uses of ammonia liquor were indicated by references to the manufacture of cuprammonium silk, to toilet ammonia preparations and to laundry and textile processes. Among other sections of this comprehensive exhibit were those dealing with the uses of ammonia converted to cyanide—fumigation by hydrocyanic acid, gold extraction and case hardening—and of ammonia as urea in the manufacture of plastics and in the pharmaceutical trade.

On the stand of Boots Pure Drug Company, Ltd., was a large diagrammatic chart, showing stages in the manufacture of fine chemicals from coal tar. Among organic reagents for metals, Hopkin and Williams, Ltd., showed resacetophenone (dihydroxy-acetophenone), a reagent for iron, and dimercaptodithiodiazole, a reagent for bismuth, which has now been recommended for the determination of lead tetraethyl in petrols. They also showed for the first time a group of fluorescent indicators, which are recommended for the determination of acidity or alkalinity of strongly coloured solutions which inhibit the use of visual indicators.

Turning to the grouped exhibits of the scientific instrument manufacturers, these, as in the last few years, formed one of the outstanding features of Olympia. It is impossible within the limits of this article to do more than direct attention to a few of the novel products shown this year. Ross, Ltd., exhibited a very remarkable wide-angled survey lens, recently produced. It has an angle of 96° and consists of a five-lens system, in which the separation between

the component lenses is $1/1000$ in. The lenses are not cemented but held in position by special clips, in order to avoid strain that might be set up by the use of a cemented lens at high altitudes where very low temperatures prevail. Moreover, the system is mounted in stainless steel having a coefficient of expansion equal to that of the glass, so as to avoid any possibility of strain or deformation due to differential temperature changes. As to the performance of this lens, a photograph was exhibited taken from a height of 20,000 ft. covering 40 square miles of London with one exposure, all the streets and main landmarks being easily recognized by the naked eye. This lens is a remarkable achievement, of which the British optical industry may well be proud. It is made of $3\frac{1}{4}$ in. focus upwards and is priced from £250 upwards. Ross, Ltd., also showed a new, extremely lightweight prism binocular with extra-wide field. The effective diameter of the object glass is 30 mm. with a real field of view of 9° and an apparent angle of 63° , and the instrument is provided with central focusing by screw adjustment.

Charles Baker showed a new micrometer measuring microscope, with a travel of 300 mm. (12 in.), reading to 0.01 mm. direct and by estimation to 0.0025 mm. The microscope is mounted on two accurately ground, stainless steel bars on the kinematic principle. The stage is also mounted on the kinematic principle and has coarse and fine adjustment in the vertical direction.

Cooke, Troughton and Simms, Ltd., showed a new geodetic level designed for the Ordnance Survey in conjunction with Major Hotine of that Survey. The body of the telescope is made of metal having the same coefficient of expansion as that of the glass incorporated. The focal length is 13 in. and the aperture of the object glass 2 in. The main spirit level—a split bubble—is read in the field of view of the telescope by the coincident method.

E. R. Watts and Son, Ltd., exhibited a new theodolite, having the following novel features: short but powerful telescope, glass instead of metal circles, the use of an optical micrometer for reading the subdivisions, an optical plummet incorporated in the body of the instrument, and the complete enclosure of the circles and optical system.

Among the exhibits of R. and J. Beck, Ltd., was a combined binocular and monocular microscope, having an inclined eyepiece. It contained means for varying the inter-ocular distance and for the change-over to the monocular without dismantling the lenses. They also showed a new model of the Hart-ridge reversion spectroscope, designed specially for the physicist. It has a symmetrical slit and is graduated to read direct into Angström units.

Among the exhibits of W. Watson and Sons, Ltd., was an apparatus known as the 'library reader'. By means of a camera a photographic record of, say, a 500-page book can be taken on only 30 ft. of standard cine film. The film can then be projected on to a screen to be read conveniently. One purpose of this apparatus is to render accessible to serious students unique manuscripts and precious early editions of books possessed by libraries, where it would be inconvenient to allow the actual books to be used.

Adam Hilger, Ltd., showed a photometric colour comparator. Its main use is for the maintenance of colour uniformity or the matching of specimen colours in various industries. It makes use of polarizing laminae, the planes of polarization of which are mutually perpendicular. It is not suggested that this instrument can take the place of a colorimeter of such precision as the trichromatic colorimeter, or of an accurate spectrophotometer, but for the diagnosis of colour faults and for colour standardization within the factory it is claimed to be of great practical value. Messrs. Hilger also showed a projection spectrum comparator. This instrument projects the images of two spectrograms—the spectrum to be interpreted and the standard spectrum—in juxtaposition upon an easily viewed screen, and so avoids monocular observation through an eyepiece. This firm also showed a spectrograph having a flat focal field, so that no adjustment of focus is required for any part of the spectrum. An incidental advantage of the flat photographic plate that may consequently be used is that the thickness

of the glass does not matter and the spectrograph is no longer restricted to the use of thin plates.

The most prominent feature of the scientific instruments exhibit, and the one, perhaps, which aroused most interest in the visitors, was the anti-aircraft predictor. This instrument computes mechanically for anti-aircraft purposes the position of an approaching target, such as a hostile bomber. It will be realized that the speeds of modern aircraft are such that it may be necessary to direct the gun as much as two miles ahead of the path of the bomber, if the projectile is to hit the 'target'. The target must be visible to the observer and, therefore, at night must be 'caught and held' by the searchlight. The telescope of the predictor is then laid on to the target and follows it, and as it does so the instrument shows automatically the position and other data required and feeds the gun crew automatically and simultaneously with all the necessary information for firing, including even directions for the adjustment of the shell fuse. To the lay visitor it must have seemed almost like black magic.

Microtechnique in Organic Chemistry

A SURVEY of the most important advances in organic chemistry during the last ten or fifteen years shows that these deal very largely with the chemistry of naturally occurring products. Perhaps the most striking developments are the determination of the structure of the principal vitamins, the very existence of which was debatable fifteen years ago, and the elucidation of the nature of the sex hormones and of the plant growth substances (auxins). No less important, if less spectacular, work has been done on new alkaloids, plant pigments, insecticides and triterpenes.

A point which cannot fail to strike the observer is that the quantities of material available for these investigations are of necessity extremely small. Thus the total amount of auxin used by Kögl in the elucidation of its structure was of the order of one gram, yet the molecule of this compound contains eighteen carbon atoms; and the majority of the other hormones and vitamins are equally or more complex.

These investigations were only made possible by the development in the course of the last two decades of a number of new experimental methods, which have revolutionized the technique of organic chemistry; thus it is now possible to carry out analyses on quantities of about 1/50 of those formerly required, whilst the degree of accuracy and reliability attainable is definitely greater.

In view of what has been said, the symposium on microtechnique held by the Chemical Society on March 2 was particularly timely and a number of new advances were discussed by specialists.

Prof. I. M. Heilbron opened the discussion and gave a general survey of the methods available to the investigator. Of these, quantitative analysis is perhaps the most important; it is to-day possible to carry out exact estimations of carbon and hydrogen, nitrogen, sulphur, halogens and the metals using 2–3 mgm. of material. Molecular weights can be rapidly determined on even smaller amounts of material by Rast's cryoscopic method, and functional groups, such as acetyl, methoxyl and *N*-methyl, can all be determined

on quantities of not more than 5 mgm. Active hydrogen can be estimated by the micro-Zerevitinov method, while the modern methods of titration are extremely accurate and can be successfully applied to such compounds as the resin acids and the saponins of the C_{30} groups. Finally, the degree of unsaturation can be quantitatively estimated and an apparatus for this purpose, designed for quantities of 1 mgm. or less, was described by Dr. H. Jackson. An improvement of Pregl's microcombustion apparatus, in which rubber connexions have been entirely eliminated without making the apparatus fragile, was demonstrated by Mr. W. F. Boston.

Absorption spectra provide a purely physical method of observation which can be of the greatest service to the chemist, as Prof. Heilbron showed on several striking examples, and necessitates only minute amounts of material. The method is particularly valuable for ascertaining the number and arrangement of unsaturated centres in the molecule; it is indispensable when dealing with the vitamins of the A and D groups, carotenoids, etc. Thus, the constitution of myxoxanthin, $C_{40}H_{54}O$ was established by Heilbron and Lythgoe with considerable certainty on the basis of its absorption spectrum although less than a gram of the pure substance was available. The existence of a new vitamin peculiar to the liver oils of freshwater fish was discovered by the spectrographic method and later confirmed by chemical means. At times it is also possible to decide between two alternative types of ring structure, as in the recent instance of α -tocopherol; the extinction coefficient of this compound was found by John to be consistent with a chroman and not a coumaran skeleton.

The determination of molecular weights of solids can be carried out on less than 1 mgm. of material, provided one or two good crystals are available, by an X-ray method which was described by Mr. D. Riley working with Miss D. Crowfoot. The method depends on the accurate determination of certain constants, namely ρ , the density of the solid, V , the volume of the unit cell in the crystal, and n , the

number of molecules in such a unit, when the relationship $\rho = nM/V$ enables us to calculate M (the mass of the individual molecule or the molecular weight $\times$ the mass of an atom of hydrogen); n is, of course, a whole number which is dependent on the arrangement of the molecules in the unit cell and can be readily ascertained by a preliminary calculation. The order of accuracy attainable is such that even the number of hydrogen atoms, always an uncertain figure when dealing with large molecules, can be determined; Mr. Riley showed how the new method has been applied to such compounds as the esters of α -tocopherol.

The application of monomolecular films in solving constitutional problems was discussed by Dr. J. Schulman in the absence of Dr. E. Stenhagen. He referred to the new method of Langmuir and Blodgett, which consists in spreading a monomolecular film on water and, by alternately dipping and withdrawing a metal plate, depositing successive 'monolayers' on the metal surface, thus enabling their thickness to be measured by an optical method. From the surface potential and apparent dipole moment measurements it is possible to draw conclusions about the nature and position of the polar groups in the molecule. The area occupied on water gives a measure of the cross-section of the molecule and it is often possible to make deductions as to the shape of the molecule, such as the extent to which a long chain is branched, which would only be possible as the result of elaborate degradation experiments. This was particularly well exemplified by the recent beautiful work on phloic acid, a toxin derived from the tuberculosis bacillus; the results provide a starting-point for synthetic work in conjunction with biological tests.

Chromatographic adsorption, which was discussed by Dr. A. H. Cook, was discovered by Tswett so long ago as 1906, but its usefulness was not appreciated until it was recently reintroduced by Kuhn, Winterstein and many other workers for the separation of carotenoids. It is essentially a preparative method and its vast scope is only just being realized. In principle it depends on the fact that many substances of comparable solubility in a given solvent differ greatly in their capacity for being adsorbed on a variety of inert materials such as alumina. When a solution containing such substances is allowed to run through a column of the adsorbent, the most readily adsorbed substance is retained nearest the top and the least readily adsorbed is found at the bottom or goes right through. With coloured compounds, such as carotenoids, it is easy to observe the process of adsorption, since rings or zones of colour are produced; the adsorbed substances can then be eluted by changing the solvent or by cutting the column up into sections and extracting each separately. The adsorption of colourless compounds can sometimes be followed by means of ultra-violet light or the zones can be made visible by adding a coloured 'indicator'—a dye of the same degree of adsorbability as the required substance. This ingenious variant of the method was used by Brockmann in the isolation of vitamin D₂ from fish liver oils. The chromatographic method is also extremely useful for the purification of countless organic compounds and has the advantage that practically no material is lost; it can be used on an almost microscopic scale, as in Schöpf's isolation of the colouring matter of butterflies' wings, or adapted to large-scale work.

G. A. R. Kox.

Steel Castings

A SESSION of the adjourned Autumn Meeting of the Iron and Steel Institute was devoted to a consideration of the extremely important third report of the Steel Castings Research Committee.

After a short introduction, Section 2 deals with the fluidity of iron-carbon and alloy steels, by Prof. J. H. Andrew, G. T. C. Bottomley, W. R. Maddocks and R. T. Percival; together with other contributions on the Ruff test by T. R. Walker and R. J. Sarjant and T. H. Middleham. The fluidity tests carried out with the standard spiral mould described in the second report of the Committee have been extended and it is evident that in this type of test temperature is the all-important factor, composition itself playing a minor part. An outstanding feature of this paper is the serious attempt made to correlate fluidity with the liquidus and solidus curves. In the Ruff test, where the test piece is a straight rod, there are certain points of difference. As an example, the markedly greater fluidity of Swedish charcoal iron as compared with that of Armco iron of similar composition, indicates strongly that the difference in oxidation of the melt is a by no means unimportant factor. The influence of oxygen is also shown in the erratic results which are obtained when deoxidants, such for instance as aluminium, are added to the steel. Trials of the test have also been carried out on an industrial scale in a large steel foundry, the results indicating that this method of measuring

fluidity gives reproducible results which are sufficiently accurate for practical purposes.

Section 3 deals with a report by Martin Alexander on copper-containing steel castings. The effect of 1 per cent of copper has been investigated in cast steels of widely different composition. The results indicate that this metal is a valuable alloying element in such materials. It improves the mechanical properties of the annealed steel and renders the castings susceptible to a hardening treatment which can be carried out at a temperature below the critical range without distortion or the setting up of internal stress. The full effect of the temper-hardening treatment, however, cannot be employed with advantage on account of the accompanying embrittlement. To avoid the undue fall in impact strength it is necessary to provide a sufficiently tough matrix by keeping the carbon content low and to re-heat the casting to a temperature higher than that giving maximum hardness in order to cause some coalescence of the precipitated constituent.

Section 4 is concerned with the strength and ductility of cast steel during cooling in sand moulds from the liquid state. The author, H. F. Hall, has devised a most ingenious, and apparently successful means of determining the susceptibility of the material to give contraction cracks. The test piece is so designed that at some position within it the temperature during cooling is maintained above that of the remainder of

the bar, while a tension is induced at an early stage by the special design of the end conditions.

Section 5, which represents the first report of the Moulding Materials Sub-Committee and extends to something like 120 pages, is a remarkable achievement for the time this Committee has been at work, and certainly represents the most important contribution yet made to the scientific and technological study of moulding sands for steel castings.

The report ends with a bibliography of some ninety pages dealing with the manufacture, properties and testing of steel castings, prepared by the Library and Information Department of the Institute. To all who have been in any way concerned with the work for, and the preparation of this report, wholehearted congratulations may be offered.

Economic Policy in the Twentieth Century

A BROADSHEET, "Twentieth Century Economic Policy", recently issued by P.E.P. (Political and Economic Planning), directs attention to the need for guiding patterns to replace the one-sided patterns of *laissez-faire* and nationalism. The broadsheet largely summarizes the attempt to provide the essentials of such a pattern which are set forth in a memorandum prepared by Prof. N. F. Hall, director of the National Institute of Economic and Social Research. Measures adopted to maintain the volume of employment have checked improvements in the standard of living and new policies are required to raise the several national standards of living without in the process setting up intolerable strains. Recent scientific advances, moreover, justify the assumption that there is a minimum physiological standard of living which can be roughly measured and which is a necessary condition of progress in other directions. The satisfaction of minimum physiological needs can be set as an immediate goal for economic policies without sacrificing other values provided the methods adopted do not infringe individual freedom.

Economic adjustment demands increasing efficiency in the older lines of production to liberate resources and particularly labour for new enterprises. The standards now available for nutrition supply a definite basis for assessing advances and setbacks as regards food. Less exactly approximate minimum standards can be ascertained for clothing, house space, and equipment necessary for physiological well-being under different conditions of climate, etc. The first step towards stable national and international progress is therefore to draw up common standards of a broad and simple character and survey the deficiencies of different countries and regions. Not only is it becoming possible to determine such minimum standards but also to forecast the actual demand for the various products in given conditions of price, income and knowledge. The key to expansion of demand lies in the relation between money incomes of consumers and the unit prices of basic necessities, which determine how much purchasing power will be available to raise consumption of all classes of goods above the level necessary for mere survival.

The cardinal aim of economic policy should thus be to reduce costs and prices of necessities, setting free margins of purchasing power which will in turn lead to reductions in the price of semi-luxuries.

Science News a Century Ago

The Statistical Society and Vital Statistics

In the annual report of the Council of the Statistical Society, read at the anniversary meeting on March 15, 1889, it was stated that the Committee on Vital Statistics was still engaged in collecting data from which may be deduced the laws of human mortality. With regard to a collection of the experience of the numerous insurance societies, the circulation of the Committee's forms among the several offices had had the effect of inducing a committee of actuaries to renew the prosecution of a previously contemplated plan for collecting the desired information. Such a committee obviously possesses peculiar facilities for the task, the report said, and as the Council had received the strongest assurance that the actuaries had the same object in view as the Society, to which they had promised to communicate the results of their labours, the proposed inquiry had been abandoned. But the Council had received some valuable returns from various medical establishments in reference to the subject, and the forms of registry suggested by the Council had been adopted in important public institutions.

Stephen Peter Rigaud, F.R.S.

On March 16, 1839, the Oxford astronomer Stephen Peter Rigaud died at the house of his friend Benjamin Lewis Vulliamy, the clockmaker, in Pall Mall, London. Descended from a family of French Protestant refugees, he was born in Richmond, Surrey, on August 12, 1774, his father being Stephen Rigaud (d. 1814), who for many years assisted the Rev. Stephen Demainbray at the King's Observatory at Kew. In 1791, at the age of seventeen years, Rigaud entered Exeter College, Oxford, and he spent practically all the rest of his life at the University. Graduating in 1797, he became a fellow of the College, a tutor and examiner. In 1810 he succeeded Abraham Robertson in the Savilian chair of geometry and was again Robertson's successor in 1827 in the Savilian chair of astronomy, and this he held until his death. Described as "a laborious student, widely read, no mean conversationalist and a copious correspondent", he is remembered for his work as a mathematical antiquary and bibliographer.

The Polypi of the Mediterranean

"The observations of M. Milne-Edwards on the Polypi of the Mediterranean," said the *Athenaeum* of March 16, 1889, "have induced him to conclude, that the horny cartilaginous or calcareous coverings which envelope them, far from being mere external crusts, without any organic connexion with the animals, which produce them, are integral parts of these beings, and consist of an organised tissue, the substance of which is more or less charged with horny or calcareous matter deposited in it; and the nutrition of which is effected by intussusception. Among all these animals there exists a tendency in their tegumentary and reproductive parts to become hard, and the degree of solidification which these parts attain is the only character by which zoologists can class them, as naked polypi, flexible polypi, etc."

Prof. Henri Milne-Edwards (1800-1885), who was the son of an Englishman, filled the chairs of entomology, zoology and physiology at the Jardin des Plantes, Paris.

Forthcoming Events

[Meetings marked with an asterisk are open to the public.]

Tuesday, March 14

CHADWICK PUBLIC LECTURE (at the Royal Sanitary Institute), at 5.30.—J. B. Howell: "The Preservation of Child Life".*

BRITISH ASSOCIATION OF CHEMISTS (LONDON SECTION) (in the Conway Hall, Red Lion Square, W.C.1), at 8.—Prof. J. B. S. Haldane, F.R.S.: "Hereditary, Chemistry and Politics".*

Wednesday, March 15

ROYAL INSTITUTION, at 5.15.—Prof. F. G. Donnan, F.R.S.: Ludwig Mond Memorial Lecture.

Friday, March 17

ROYAL INSTITUTION, at 9.—Dr. W. H. Hatfield, F.R.S.: "New Researches in Steel Metallurgy".

Appointments Vacant

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN MATHEMATICS in the Rugby College of Technology and Arts.—P. I. Kitchin, 61 Clifton Road, Rugby (March 16).

TEACHER OF ENGINEERING, MATHEMATICS, SCIENCE AND DRAWING in the Oxford Schools of Technology, Art and Commerce.—The Chief Education Officer, City Education Office, 77 George Street, Oxford (March 17).

LECTURER IN MATHEMATICS AND ELEMENTARY PHYSICS in the Polytechnic, Regent Street, W.1.—The Director of Education (March 20).

UNIVERSITY PROFESSOR OF THE PATHOLOGY OF MENTAL DISEASE in the University of London.—The Academic Registrar, University of London, Senate House, W.C.1 (March 23).

ASSISTANT in the University of London Observatory.—The Director, University Observatory, Mill Hill Park, N.W.7 (March 24).

SENIOR ASSISTANT in the Department of Mining, School of Metalliferous Mining (Cornwall), Camborne.—The Secretary (March 29).

No. 3620

Organization and Development of Museums

IT is keeping within the truth to say that in Great Britain and Ireland a new museum is born every three weeks, roughly twenty in a year, or two hundred since Sir Henry Miers's report to the Carnegie United Kingdom Trustees was published in 1928. That is an index to the enthusiasm of groups of people aware that there are hidden things the public ought to see ; but, alas, it is no index to the foresight of the enthusiasts, for the history of museums indicates that many of the new foundations, without endowments or any guarantee of permanent backing, will sooner or later drop out of the running and disappear. The death-rate of museums all but keeps up with the birth-rate ; but the spectacle of the lingering death of the idea embodied in a collection which has outlived its interest does infinite harm to the museum movement.

Museums die because the people do not want them, at any rate in the form which their presentation too often takes ; and if only the secret of a live interest could be discovered, and the discovery were rigidly and universally applied, a new page would be opened in the museum story. A great contribution towards this end is made in S. F. Markham's recent report to the Carnegie United Kingdom Trustees*, a book which ought to be pondered over by everyone interested in the present condition and potential future of the museums and art galleries of Great Britain.

The origin of the report is of historic interest. Ten years ago, Sir Henry Miers wrote the first thorough-going account of the museums of Great Britain, also for the Carnegie United Kingdom

Trustees, and having exhibited the pitiful shortcomings of the museum service, which in his opinion required complete reformation, he made suggestions for improvement along three lines—by individual effort on the part of museum authorities, by co-operation, and by the helping hand (or purse) of external bodies. Anyone who takes the slightest interest in these public institutions must be aware of the stimulus Sir Henry Miers's investigation gave to the museum movement and the progress in certain directions made during the decade which has elapsed.

Mr. Markham acted as secretary to Sir Henry Miers ; he has since carried out a survey of museums in most of the British Dominions and Colonies and in India, on behalf of the Carnegie Corporation of New York ; so that no one could have been better equipped for the new British survey which the trustees desired to make, in order to assess the progress of the past ten years and to foreshadow the needs of the future.

Many years ago (1889), Sir William Henry Flower, in his presidential address at Newcastle-on-Tyne to the British Association for the Advancement of Science, defined the purposes of a museum as the advance or increase of knowledge in some given subject, and the diffusion of knowledge among the interested public—in short, the two aims of research and instruction. Half a century has seen great developments in museum standards, but the aims remain essentially the same. The first great purpose is to collect and conserve objects of historic, scientific or artistic importance for our own and future generations ; there follows the furthering of specialized knowledge by research in these collections, the more recent and very

* A Report on the Museums and Art Galleries of the British Isles (other than the National Museums), by S. F. Markham. Pp. 311 + 179 + 24 plates. (Dumfriesline : Carnegie United Kingdom Trust, 1938).

insistent aim of the education of the people by attractive exhibits, and the ultimate ideal of stimulating love of beauty or endeavour in some branch of human achievement.

Every museum cannot compass all these objects, but every museum must set out with its objective clearly conceived and must bend its activities to the accomplishment of its particular goal. But the goal is never attained. The essence of museum success—even of museum existence—is perpetual striving and continuous progress. The only type of museum which can afford to remain static is that devoted to perpetuating the memory of a great personage—Shakespeare, Livingstone, Wolfe, to mention recent examples—where personal relics are bound to be limited in number, and where the attraction is predominantly emotional rather than educational. These, however, form a relatively small proportion of Great Britain's museums: of our eight hundred museums, "about 165 are devoted to a historical or personal theme, 100 to natural history alone, about 80 to art, 20 to medicine, and 20 to industry. The remainder, therefore, totalling some 400 museums, are general in their character, though many, probably 150, have a distinct emphasis upon illustrating their immediate environment" (p. 52).

Sir William Flower wisely said, in the address referred to, "A museum is like a living organism—it requires continual and tender care. It must grow, or it will perish." We would prefer to say 'develop' rather than 'grow', for there is an impression that the addition of new rooms always means progress, whereas extensions may actually hinder the development constantly required in any collection. But the plain fact is that museums die (and we know of collections excellent in their day, and their day opened nearly a century ago, disappear in recent years) because they have become moribund—activity, the breath of life, has departed from them long ago.

The first essential for a developing museum (and all others are moribund) is a competent curator, who has the knowledge, the skill and the brains to plan and execute; and a competent curator deserves his reward—he may at least expect a living wage. Yet, apart from a hundred and forty out of more than eight hundred museums in Great Britain, "in nearly every other case the curator is paid a scandalously low salary". There are pitiful examples mentioned by Mr. Markham of salaries of £50 recently raised to £75 or to £100 a year. The County Borough of West Ham (population

294,000) offered £155 per annum for "a full time assistant with biological training, knowledge of photography, and a Science degree (not essential)"; the County Borough of Reading (population 100,000) advertised for "a male assistant with practical Museum and Art Gallery experience, not under 22 and preferably registered for the Diploma, salary offered £115". And the London County Council pays its dust-collecting gangers £158 and its dustmen £150 a year! Is it surprising that dust accumulates and men and ideas decay in some of the provincial museums?

The ten years which have passed since Sir Henry Miers made his recommendations have emphasized the backwardness of the weaker museums (nearly four hundred and fifty in number), since the better institutions have taken advantage of new opportunities and have pushed ahead. There is closer co-operation between them, expressed in flourishing regional federations, and in the growing power of the Museums Association; they have been aided and advised to a greater extent by the national museums; and they have made more use of the development of exhibition technique, to the great benefit and the educational value of their halls and galleries.

The increasing museum contribution to education in progressive institutions has indeed been one of the impressive features of this century. Not only have greater efforts been made to replace dull collections by displays in which art and science blend for the attraction and instruction of the public, but a deliberate attack upon indifference has also begun. Temporary exhibits of objects of particular interest, special exhibitions illustrating achievements of, or developments in, art and science, the increasing use of modern methods of publicity, in which the newspapers have proved loyal helpers, the encouragement of regular school visits, and the circulation of loan collections among schools—all these devices have become part of the recognized services of museums to the public; and the public has responded by showing a new and increasing interest in museums.

But something still is lacking. Efforts tend to be spasmodic and confined to comparatively few centres; improvements are costly, and municipalities and private bodies are already hard put to it to find the funds required, even if they were sure of the most desirable lines of advance; and there are museums that are static, because no interest is taken in them. If the country's museums over all are to be made worthy of the

great purposes which it is in their power to serve, some beneficent *deus ex machina* must appear to weld the scattered units into a national movement. Whether that kindly guiding power shall be vested in a Government department, or shall emerge from the museums themselves by way of the Museums Association, it is essential that it should have two basic functions: first, that of giving advice where advice is sought, and of making recommendations where museums are moribund, and secondly, that of subsidizing improvements and encouraging developments by the use of

moneys allocated by Government for museum purposes.

So, as Mr. Markham says: "In the mind's eye one can see organised throughout the length and breadth of the country temples of vision, where young enthusiasts will find a ready welcome and a helping hand with a colossal book of knowledge; schools will have auxiliaries on the cultural side not less than those which playing-fields now give them on the physical side, and adults will find in these centres a combination of relaxation, interest, and ever-widening horizons."

The Scientific Work of Charles Fabry

Œuvres Choiesies

Par Charles Fabry. Publiées à l'occasion de son jubilé scientifique. Pp. vi+695. Jubilé scientifique de M. Charles Fabry célébré à la Sorbonne le 3 décembre 1937. Pp. 96. (Paris: Gauthier-Villars, 1938.)

WHEN, in 1937, Charles Fabry retired from his professorship in the University of Paris, he was persuaded to arrange and edit his principal scientific papers. The "*Œuvres Choiesies*" is the result.

It is an impressive record, not so much from the actual amount of reading matter, though that is considerable, but because the author by selection and compression has been able to present an adequate record of the main results of half a century's research in about two hundred and fifty thousand words.

Before we attempt to summarize the contents of the book, let it be said at once that Fabry's love of research was accompanied by a devotion to teaching. He has said himself: "Toute mon existence a été consacrée à la Science et à l'enseignement, et ces deux grandes passions m'ont procuré les plus vives joies." There are, perhaps, not many teachers who could refer to their vocation with such enthusiasm; but all would agree that it is a great consumer of time and energy. In assessing the magnitude of Fabry's work one must read between the lines of his paper a story of tireless activity as an inspiring and greatly loved teacher.

To return to Fabry's "*Œuvres Choiesies*". He was only about twenty years old when he took a post at the Faculté des Sciences at Marseilles under Macé de Lépinay. It was not long before the two published in collaboration a paper on the "Théorie

générale de la visibilité des franges d'interférence" (1891). Thus early the keynote was struck which was to echo through so much of Fabry's work—more than half the book is concerned with the phenomenon of the interference of light and its application to the solution of physical problems.

About five years later, Fabry commenced to study the interference fringes of silvered plates in collaboration with A. Perot, and in 1897 they published the first important description of the Fabry-Perot type of interference fringes and their use in the measurement of length.

This was the type which Fabry always used thereafter, its advantage lying in the much greater fineness of the fringes as compared with those used, for example, by Michelson.

In a series of papers, Fabry and Perot described the properties of these fringes; how to determine the number of the order of a fringe corresponding to a large path difference, how to use them for the measurement of lengths up to several decimetres, and for the comparison of wave-lengths of different rays (1898 and 1899). They then applied the method to determine the size of a 4 cm. cube of quartz in wave-lengths of cadmium red light, and with Macé de Lépinay determined by its aid the mass of a decimetre of water. Other papers on interference metrology finally led, in 1907, to the epoch-making "Nouvelle détermination du mètre en longueurs d'ondes lumineuses" and the "Détermination de la longueur d'onde de la raie rouge du Cadmium".

This determination led to Benoît, Fabry and Perot making, in 1907, at the Conference of the International Union for Co-operation in Solar Research at Meudon, the following recommendation: "La longueur d'onde de la raie rouge de la lumière

du Cadmium produite par un tube à électrodes est 6438,4696 Angström, dans l'air sec 15° du thermomètre à hydrogène à la pression de 760 mm. de mercure, la valeur de g . étant 980,67 (45°). Ce nombre sert de définition à l'unité de longueur d'onde."

This recommendation was adopted by the Conference. Twenty years later (1927) the determination was officially recognized by the Comité (and later by the Conférence générale) du Bureau International des Poids et Mesures as still the best. In June 1936, Fabry was able to show at a session of the same Committee that, applying certain new corrections discovered at the Reichsanstalt, the measurements were in excellent accord with the latest made at Teddington and at Berlin.

Fabry and Perot then turned their attention to the use of their étalon for determining wave-lengths. Previously the wave-lengths of rays had been found by comparing their positions in a spectrum with those of other rays the wave-lengths of which had been determined by Rowland from the measured dimensions of a grating. Fabry and Perot set themselves to determine a number of wave-lengths by comparison with one selected ray, with all the accuracy attainable with their new method.

The technique for carrying out this work was published during the years 1898-1900, a further application being added, that, namely, of determining in a like manner the wave-lengths of the Fraunhofer lines of the solar spectrum. In 1902 they published thirty-three wave-lengths of the solar spectrum determined in this way, together with the wave-lengths of a number of metals, including iron; altogether more than sixty wave-lengths being given to the seventh decimal place.

In a subsequent paper (1905), they described their more expeditious way of determining intermediate wave-lengths by forming an image of the diffraction pattern yielded by one of their étalons on the slit of a spectrograph.

To apply the method to measurements of extremely small variations of wave-lengths was but a short step, and Fabry and Buisson in 1910 studied in this way such problems as the widths of the line of the solar spectrum, the Doppler-Fizeau effect on rays from the circumference and middle of the solar disk, the kinetic theory of gases, and the internal movements of the Orion Nebula. Differences of line of sight velocities present in the nebula were determined to a much greater accuracy than had before been possible.

To study the Doppler-Fizeau effect in the laboratory, Fabry devised a very ingenious piece of apparatus, using a revolving disk of white paper

as the means of producing a moving source of light.

There is no space to deal here with minor applications of interferometry, such as the determination of the voltage of a Latimer-Clark standard cell in absolute electro-static units.

The next section of Fabry's work became of great practical interest in the highly technical problem of heterochromatic colorimetry. This presented difficulties which increased with every new source of illumination.

Fabry put forward the suggestion in 1903 that the problem should be simplified by the use of liquid colour filters which, placed between the standard lamp and the photometer, gave a colour match with the lamp to be measured. The transmission of the filters could be carefully determined once for all to the necessary accuracy, and then all subsequent measurements could be made under conditions involving no colour difference. When he put forward this suggestion at the Academy of Sciences in November 1903, it met with great opposition—indeed, the member who presented the note for Fabry wrote to him that he did so only "après beaucoup d'hésitation". Nevertheless, in a few years the method was accepted throughout the world, as were also the views on the universal unit of illumination, put forward by Fabry in his report on the subject to the International Commission on Illumination in 1921.

Lack of space forbids more than a mention of Fabry's work in astrophysics in connexion with photometry of the sun, stars and night sky, and the diffusion of light by gases; but something more must be said concerning his study of the ultra-violet end of the solar spectrum. In a preliminary investigation he came to the conclusion that the limit to the ultra-violet spectrum of the sun results from three causes: molecular diffusion, scatter by dust or other fine particles, and absorption by ozone; and he then proceeded to work out a technique whereby the amount of ozone could be measured.

Such measurements are now regularly made in the manner developed by Fabry. The theory had long before been put forward by Hartley that the limits of the solar spectrum were due to ozone, but no measurements had been made previously to Fabry's in support of this hypothesis.

In 1937, Prof. Charles Fabry was seventy years of age, and on the occasion of his jubilee celebration he told his audience that he was accustomed to using logarithmic tables at the age of eleven years, and could almost say that he learnt to read from the "Annuaire du Bureau des Longitudes". His undiminished ardour and vitality permit us to hope that he only closes this volume to commence a fresh one.

F. TWYMAN.

Explorations in Climatology

(1) Handbuch der Klimatologie

Herausgegeben von W. Köppen und B. Geiger. Band 4, Teil T: Klimakunde der Südsee-Inseln, von Prof. Dr. G. Schott; und Band 4, Teil U: Klimakunde der Antarktis, von Prof. Dr. W. Meinardus. Pp. T114 + v + U133. (Berlin: Gebrüder Borntraeger, 1938.) 40 gold marks.

(2) Die Meteorologie des Sonnblicks

Teil 1: Beiträge zur Hochgebirgsmeteorologie nach Ergebnissen 50 jähriger Beobachtungen des Sonnblickobservatoriums, 3106 m. Von Ferdinand Steinhauser. (Herausgegeben vom Sonnblick-Verein.) Pp. 180 + 1 map. (Wien: Julius Springer, 1938.) 8 gold marks.

(1) **THIS** part of the great "Handbuch der Klimatologie" contains two sections, the South Sea Islands and the Antarctic. In spite of their apparent total dissimilarity, these two regions are alike in being represented by few and scattered climatological data, which are none the less impressive because they show the interaction of meteorological forces on a scale seen in few other parts of the earth.

The equatorial Pacific is the meeting-place of two great converging wind systems—the north-east and the south-east trades—which have swept over thousands of miles of tropical ocean and are hot and humid. By the canons of meteorology, convergence means forced ascent, and the meeting-place of the winds would therefore be expected, and was long supposed, to be a region of frequent and intense rainfall. Observations have shown, however, that the actual meeting-place of the winds is on the whole an arid region with a violently fluctuating rainfall which may sink almost to zero for months at a stretch. The expected heavy rains fall on either side of this dry strip, but especially to the southward, where the transition is very rapid. It is an interesting problem in the effects of air masses, to which the author recurs several times, though he does not bring out clearly the remarkable relation between wind direction and rainfall.

In the well-known trade winds themselves the rainfall on the small mountainous islands is almost entirely orographic. The steady winds and the rugged topography bring this out with almost startling emphasis, as, for example, in Oahu, Hawaii, where the annual rainfall varies from more than 236 inches on the peaks to less than 20 inches on the leeward shores. Incidentally, the rainfall charts for the

Hawaiian islands are rather confusing because some are given in centimetres and one in millimetres.

The ice-covered Antarctic continent and the surrounding seas provide a great natural laboratory of a different type, where emphasis is laid on the effects of temperature. The author takes as the boundary of the sub-antarctic region not the shifting and uncertain limit of ice but the much more regular 'convergence line' where the cold antarctic waters meet the warmer seas of the main Southern Ocean. He thinks that it is the contrast of temperature across this boundary which provides most of the energy for the continuous storms of that region. The rest of the energy comes from outbreaks of cold air from the ice-covered continent, but these are confined to three separate regions. Elsewhere the outflowing winds are deflected by topography into great eddies the courses of which are reflected in the streams of drift ice. There is an interesting analysis of the conditions along the boundary between the antarctic and maritime winds, the more or less continuous antarctic polar front, but all this part of the earth is still rich in unsolved meteorological problems, both at the surface and in the upper air.

Both sections are well provided with diagrams, and all available statistical information is set out in the numerous tables which are a regular feature of the "Handbuch". In the Antarctic section perhaps a little too much is made of the scanty data by harmonic analysis, and one would have preferred more quotations of descriptive passages. There are very full bibliographies in both sections.

(2) The completion at the end of 1936 of an unbroken series of meteorological observations covering a period of fifty years, at a height of 10,190 ft. on the summit of the Sonnblick, marks a magnificent achievement, great not only for the scientific value of the results but also in terms of sustained effort against the difficulties of Nature, which can readily be appreciated from the coloured panorama slipped inside the front cover. This volume presents a summary of the climatological results with a wealth of detail.

The elements discussed include temperature, humidity, cloud and sunshine, precipitation, wind and pressure. The mean temperature for the year is only 20.5° F., falling to 8° F. in February, while only two months, July and August, have a mean just above the freezing point. Greater interest is attached to the secular variation. As is now well

known, the first fifteen or twenty years of the present century were mainly a period of mild winters and less definitely of cool summers in Europe. The same tendency is shown by the Sonnbliek observations, proving that this change is not confined to the lowest layers of the atmosphere.

In humidity the mountain-tops present some unusual phenomena of the 'looking-glass' sort. Relative humidity is greatest in summer, and in summer it is greatest in the evening and least in the morning. This is because the whole layer of air below contracts during the night and expands during the day, while irregular movements cause some very rapid changes from one hour to the next. Cloudiness shows similar features, being greatest in summer, especially with easterly winds! Even the duration of sunshine is greater in March than in June but varies little throughout the year,

while the percentage of possible sunshine is greatest in February and January. Sonnbliek well supports the famous winter climate of the high Alps; Vienna presents a very different picture.

Mountain stations were formerly important as the only source of information about the winds at high levels and they are still valuable to control and supplement the pilot balloon observations. Sonnbliek has a cup anemometer, and the results have already been the subject of some important memoirs. The present publication gives the results of the tabulations in great detail.

The discussions are supplemented by an impressive appendix containing full series of the monthly values of all elements, which will prove very valuable for reference. The whole work will appeal not only to meteorologists but also to all who know and love the Alps in their many moods.

C. E. P. B.

Egyptian Prehistory

Cemeteries of Armant I

By Sir Robert Mond and Oliver H. Myers. With Chapters by F. J. C. Baly, Dr. A. J. E. Cave, Suliman Huzayyin, Dr. J. W. Jackson, and Rev. De Lacy O'Leary, and other Contributions. The Text. Pp. xiii + 300. The Plates. Pp. xi + 78. (London: The Egypt Exploration Society, and Oxford University Press, 1937.) 25s.

IT is a far cry from digging treasures centuries ago to modern excavations, and between the first memoirs of excavations in Egypt and this book there is almost as great a difference. Its results are of interest not only to archaeologists but also to students of natural science.

"Cemeteries of Armant I" is a report on the excavation of, for the most part, prehistoric cemeteries at Hermonthis (Armant) in Upper Egypt. There is also an account of a prehistoric settlement. In its production many experts have collaborated, with the result that it is not a mere survey of work done in the field but an attempt to apply new principles to the study of Egyptian archaeology.

On one hand, the writers employ technological and chemical tests to a great—almost too great—extent in order to get the best out of "material of no outstanding value". They describe how beads were manufactured, and the different qualities of the brickwork which was used in

tomb construction. They have analysed, by different methods, certain unique pieces of stuccoed linen found in a prehistoric tomb, perhaps a kind of primitive cartonnage similar to that which was used in later times for the covering of mummies. There are also metallurgical analyses and chapters on the anatomical study of human remains carried out *in situ*. Far-reaching theories concerning climatic changes in Africa are founded on the discovery of a new kind of pottery and traces of tree-remains in the desert sand. A valuable addition to archaeological technique is the introduction of a colour-chart, based on the "Ostwald Colour Album", in order to facilitate the accurate description of the colours of beads and pottery.

Another characteristic feature of the book is the authors' emphasis on the need to improve the systems of classification hitherto current in Egyptian archaeology, or to substitute new systems for the old. They suggest, for example, a new typology for pottery. Instead of arranging the pots in the first instance according to their pattern and shape—the system used by classical archaeologists which Petrie introduced into the study of prehistoric pottery—they are to be classified primarily by 'ware', and only within that grouping by the orthodox method. The authors also criticize the two systems of classifying beads which are at present in use, but have not attempted to devise another because of the comparatively small

number of beads found in their own excavations. A long chapter is devoted to flint implements, of special importance since there is as yet no comprehensive account of the Egyptian flint industry. Only flints from Armant are treated here, but they are classified and illustrated in a way which it is hoped will provide a basis for all future work on flints. At the end of each chapter is a useful index of the objects discussed in it.

The whole book is distinguished by a thoroughness and a scholarship which does not shrink from

confessing that the only iron ring found during the excavations—of which there is a photograph on one of the plates—was lost on the way to the laboratory! Nor are the authors afraid to state conclusions that are entirely negative.

This report of a single excavation is little short of a text-book alike for excavators and students of Egyptian prehistory, and should be studied by all who undertake research in the subject; even if, as is stated in the first chapter, "the parts are greater than the whole".

K. B.

The Ways of the Red Deer

A Herd of Red Deer

A Study in Animal Behaviour. By Dr. F. Fraser Darling. Pp. x+215+8 plates. (London: Oxford University Press, 1937.) 15s. net.

OF the large land mammals which originally inhabited the British Isles, civilization has left as sole survivors the deer, and of these the red deer, saved from extinction because of their value throughout the ages for the chase, have been studied perhaps more than any other British mammal. Yet there was more to be done. The growing appreciation of the oneness of an animal with its environment, animate and inanimate, demanded that a closer reckoning should be made between vital reactions and the condition or combination of conditions with which they were associated.

Dr. Darling has accomplished this "study of animal behaviour" with painstaking thoroughness and devotion. For two years he lived with the deer in the wilds of Wester Ross, following their movements and studying their activities at all seasons and under all sorts of conditions; as a result he has contributed and added precision to our knowledge of their natural history, and by emphasizing the relationship between weather and movement and the influences of communal life has opened up a new field of interest and speculation.

A main thesis developed in the book is the importance of the hind as a leader in the deer community: "the stag never attains to leadership, and the first stag in rut which may be running round a group of fifty hinds has no power of leadership"; but "the outstanding feature of the hind group is its cohesion which, doubtless, is derived from the stability of the family". Many telling examples are given of the supremacy of the leader hind in her own coterie, as controller

in advance and retreat, as watch and ward; even in the harem of the rutting stag the hind still retains her leadership in spite of the "egocentric and casual dominance of the stag". To this social system in a gregarious community the author applies the term "matriarchal".

The analysis of the differences between the behaviour of stag and hind groups, of their selection and use of distinct territories, and of the influences of atmospheric moisture and wind upon herd movements are valuable contributions to the ecology and reactions of the red deer. Although physiological speculation has perhaps outrun the evidence, the factual description of the phases of reproduction and of their bearing upon the sociality of the species is thorough and suggestive.

The book appears to have been written somewhat hurriedly, and inaccuracies have crept into the text: poplar trees are not "relics of a golden age of pine forest" (p. 12) judging by pollen statistics, and the pine forest of the peat did not follow upon the last glacial period (p. 15); to state boldly that Rowan's experimental crows flew *northwards* (p. 155), when the majority did not, is somewhat distorting the evidence; the map of the distribution of red deer in Scotland (p. 28) omits the interesting colony in North Uist; and it seems inconsistent to state that "man has been at pains to breed out the social instincts" of sheep (p. 95), and on the following page to say that the primitive or wild type has no flocking instinct. Sometimes, too, assertion goes further than is warranted.

Dr. Darling's book is attractively written, and he has made out a good case for "taking sociality into account in observing and interpreting behaviour"; his work will remain an example of how such observation may and should be carried out in the haunts of a wild creature.

(1) Spontane und Strahleninduzierte Mutabilität. Von H. Stubbe. (Probleme der theoretischen und angewandten Genetik und deren Grenzgebiete.) Pp. 190. (Leipzig: Georg Thieme, 1937.) 6.80 gold marks.

(a) Erbschädigungen

Von Dr. Gerhard Schubert und Dr. Artur Pickhan. (Probleme der theoretischen und angewandten Genetik und deren Grenzgebiete. Herausgegeben von H. Böhm, G. Gottschewski, W. Hüttig, G. Just, A. Pickhan, W. F. Reinig, O. H. Schindewolf, H. Stubbe, N. W. Timoféeff-Ressovsky, F. von Wettstein, K. G. Zimmer. Redigiert von W. F. Reinig.) Pp. 164. (Leipzig: Georg Thieme, 1938.) 6.80 gold marks.

THESE two volumes belong to a series dealing with the problems of theoretical and applied genetics.

(1) The first, by Dr. Stubbe, is a detailed account of spontaneous and induced mutations in animals and plants, but with the main emphasis on X-ray mutations. The results in this field are carefully analysed, and the methods used in such work are described, especially as regards dosage and length of exposure. The book will be useful for reference by all workers in this subject.

(2) The second volume, edited by medical workers, covers part of the same ground as the first. Beginning with introductory chapters on the groundwork of genetics and the nature of mutations, the third chapter discusses the genetics of wild populations in relation to isolation and selection. Chapters iv and v are concerned with the production of mutations by various types of radiation and by other physical and chemical means. The concluding chapters discuss the genetic bases of germinal injuries and defects, with particular reference to conditions in man. The mutation frequency in man and the relative importance of different types of radiation therapy are considered.

Pascal

The Life of Genius. By Morris Bishop. Pp. xii+398+6 plates. (London: G. Bell and Sons, Ltd., 1937.) 12s. 6d. net.

WE have very few books in English about this great French thinker, who has always had an extraordinary following on the Continent. Prof. Bishop's study is therefore most welcome. The various aspects of Pascal's personality are studied in turn: a thinker, a mystic, a philosopher, a physicist, a mathematician, a theologian, a man of the world, Pascal had many interests and must be credited with many achievements. These, however, are not considered quite so eminent by the author as to justify the usual estimate of Pascal's genius as one of the first rank. In science, in particular, Pascal did not do so much as some other of his contemporaries: by stressing the importance of intuition, with due regard to the claims of experience in physics, and of formalism in mathematics, it would appear that Pascal was ultimately concerned more with religion than with positive knowledge.

The attraction of man towards the infinite is, indeed, the mainspring of Pascal's thought: his theories and thoughts are really illustrations of this

leading conception of man's destiny. Prof. Bishop is therefore right in suggesting that Pascal's work is more significant for the history of religious thought than otherwise. In this respect, he rightly sides with the Jesuits against the Jansenism of Port-Royal. In spite of the light thrown by the author with excellent scholarship on Pascal's personality, the impression remains that Pascal emerges rather smaller from this scrutiny. But this, of course, is not the wish of the author of this excellent work.

T. G.

Lac Cultivation in India

Being a second and revised edition of "A Practical Manual of Lac Cultivation". By P. M. Glover. Pp. vii+147+25 plates. (Namkum: Indian Lac Research Institute, 1937.) 2 rupees.

IT is tolerably well known that lac is a resinous substance secreted by a scale insect (family Coccidae) known as *Laccifer lacca* (Kerr.). The production of lac is virtually a monopoly of India and Burma. The greater amount of lac is produced in Bihar: outside India, lac is grown in small quantities in Ceylon, Java, Borneo, Malay States, Siam, China and Indo-China.

A great deal of biological and practical work respecting lac and the lac insect has been carried out at the Indian Lac Research Institute at Namkum, Ranchi, Bihar. The results of this work are embodied in this book, now under notice, written by Mr. P. M. Glover, entomologist to the Institute. Its first edition appeared in 1931 but, since that time, conditions affecting the lac industry have changed very considerably including, more especially, the plantation growth of lac. The whole subject is very comprehensively treated by Mr. Glover, particularly from the cultural and commercial points of view, while essential knowledge regarding the biology of the insect and of its parasites and predators is not overlooked. The book is well printed and fully illustrated, while its low price should ensure its continued success.

A. D. I.

The California Woodpecker and I

A Study in Comparative Zoology. By William Emerson Ritter. Pp. xiv+340. (Berkeley, Calif.: University of California Press; London: Cambridge University Press, 1938.) 16s. net.

THE acorn-storing of the California woodpecker is of great interest, as storage of food for use at a distant date is very rare among birds. The woodpecker drills holes in the bark of a tree, and fits an acorn tightly into each—big end outward. Sometimes the natural corrugations of the bark are used, or the cracks in a telegraph pole. The drilled surface often becomes covered with a mosaic, of perhaps 50,000 acorns on a single trunk. This behaviour provides the starting-point of the present study, and the first part of the book is mainly ornithological. It then forms the basis of an essay in comparative zoology and psychology, in which bird and man are contrasted, and leads finally to a philosophical discourse under the caption "My Understanding of Men and Woodpeckers".

A Living Fish of Mesozoic Type

By Dr. J. L. B. Smith, Rhodes University College, Grahamstown

EX Africa semper aliquid novi. It is my privilege to announce the discovery of a Crossopterygian fish of a type believed to have become extinct by the close of the Mesozoic period. This fish was taken by trawl-net at a depth of about 40 fathoms some miles west of East London on December 22, 1938. It was alive when caught, and shortly after it died it was handed over to Miss Courtenay-

mounted specimen, a responsible citizen-angler of East London stated that about five years ago he had found precisely such a fish, only considerably larger (*sic*), partially decomposed, cast up by the waves on a lonely part of the shore east of East London. When he returned with assistance, the monster had vanished with a risen tide. With regard to the present specimen, fortunately both

COELACANTHID FISH FROM EAST LONDON, SOUTH AFRICA.

The small arrow shows the position of the spiracle, and the dotted line indicates the position of a membrane behind the first dorsal fin.

Latimer, curator of the East London Museum. Miss Latimer wrote to me, enclosing a sketch and brief particulars of the specimen. Owing to the seasonal disorganization of the postal services, the letter did not reach me at Knysna, some four hundred miles away, until ten days later. It was obvious from the sketch and notes that the fish was of a type believed long extinct. Immediate telephonic communication with the East London Museum revealed that, owing to lack of preserving equipment at that Institution, the putrefied body had been disposed of beyond any hope of redemption, and the fish had been mounted by the local taxidermist.

Since the fish was unquestionably alive when caught, there is at least a possibility that this zoological tragedy may be ameliorated by the capture of another specimen. This is not so remote as might appear. After careful inspection of the

Miss Latimer and the taxidermist were drawn to observe details of the carcass very closely, so that exhaustive independent questioning has left me with at least some definite information about the missing parts. Fortunately also, the terminal caudal portion of the vertebral column and part of the pectoral girdle remain. The skull is of course intact.

The specimen is 1,500 mm. in total length, and weighed 127 lb. when caught. The colour was a bright metallic blue, which has faded to brown with preservation.

In major characters this remarkable specimen shows close relationship with the Mesozoic genus *Macropoma* Agassiz, of the family Coelacanthidae, order Actinistia. The gephyrocoercal tail with protruding axial supplement, the normal first dorsal, the obtuse lobation of the remaining fins, the ganoin tubercle ornamentation on the scales and on some of the dermal bones of the head, the

nature and arrangement of the dentigerous bones of the mouth, and the form of the dermal armour of the head, are all typically coelacanthid.

The skeleton was cartilaginous, the vertebral column apparently tubular, and the whole fish extraordinarily oily. The fish has small spiracles situated as shown in the accompanying illustration, and a definite though not very obvious lateral line, which continues uninterrupted to the end of the supplementary caudal. Other differences from the known coelacanthid fishes are the pronounced pedunculation of the lobate pectorals, the reduction of the dermal armour of the head, and the presence of two small heavily ornamented bones at the anterior lower corner of the opercular plate, which probably correspond with the more fully developed inter- and sub-opercula of teleosts, also a similar posterior post-spiracular ossicle. Dermal parafrontals are not visible. There is a

free tongue composed of four fused segments covered with presumably ossified tubercles.

It is probable that systematists will wish to propose a new family (some even a new order) for this fish, but I am at present satisfied that it is close enough to the Mesozoic Coelacanthidae to justify its inclusion in that family. It has been noted that certain coelacanthid fishes underwent little apparent change from the Devonian to the Cretaceous. It is therefore not surprising that this species, which presumably has survived from the Mesozoic, should still retain most of the features which characterize that family.

For the fish described and figured above I propose the name *Latimeria Chalumnae* gen. et sp. nov.; the full account of the species and of its taxonomic relationships will be published in the *Transactions of the Royal Society of South Africa*.

A Tentative Land Fertility Map of England and Wales*

By Dr. L. Dudley Stamp,

Director of the Land Utilisation Survey of Britain

INDUSTRIAL and housing development in England and Wales is estimated to have absorbed since 1900 no fewer than 800,000 acres—an area equivalent to the counties of Buckingham and Bedford combined. This land has been taken mainly from that devoted previously to agriculture and, once covered with bricks and mortar, it is lost to agricultural production for ever. Not only is the area concerned 2 per cent of the total area of the country, but it is also largely the best quality land. The modern factory with its horizontal layout requires level or gently undulating land, preferably well-drained; such land is also that most easily and cheaply developed as building estates and is also of the type required for aerodromes. It is precisely the best ploughland which has these characteristics and which is therefore being absorbed with alarming rapidity. Amongst the assets of the nation, its good agricultural land is surely one of the most precious, and yet, at the present time, enjoys little or no protection.

First-class arable land, suitable for intensive use as market gardens, occupies a strictly limited area in Britain—probably not more than 5 per cent—yet the value of even this land for agricultural purposes is below its 'development' value

if it is so situated as to be suitable for housing or industrial purposes. Similarly, local and other public authorities take such land without hesitation for housing, recreation or public utilities (notably reservoirs), thus impoverishing national resources as a whole. Under the Town and Country Planning Acts, most agricultural land is 'zoned' for housing independently of its value for food production. Indeed, many town and regional plans completely ignore agricultural values and, as in the case of the South Essex regional plan, would result in the best land being devoted to housing and industry before the poorer land is touched. It is becoming increasingly apparent that, in the matter of land planning, local and national needs are in direct conflict, and that a National Planning Board is an urgent necessity.

If the national stability depends in any way on the maintenance and perhaps increase in home food production, and if the national health can be related in any way to a supply of fresh milk, vegetables and fruit, then the appropriate land must be preserved. The determination of the areas of best land thus becomes a problem of greatest urgency.

Several different bases might clearly be adopted in attempting a classification of the land of Britain. It might be made on the basis of a detailed soil survey, but this has not yet been made and there remain technical difficulties, including both finance

* Summarized, by permission, from a report prepared at the request of the Royal Commission on the Geographical Distribution of the Industrial Population and included in a public lecture delivered at the London School of Economics on January 31.

and personnel. Another method is to take agricultural productivity, but this is only valid if crop yields are studied on a field-to-field basis or carrying capacity of grassland on similar small units. Conclusions based on statistics available—even if individual farm or parish figures are used—are far too generalized because of the inherently heterogeneous character of the units. A survey of land values at a given time might seem to indicate a suitable basis were it not that these are related too closely to considerations of accessibility and to amenity or 'development' values. In a country where natural or semi-natural vegetation is still dominant an ecological survey may well, as F. E. Clements has urged, assess the combined total influence of all natural factors—of elevation, aspect, drainage, soil, climate. This method can be applied to the great moorland and 'rough grazing' areas of Britain and has been extended by Stapledon and his co-workers to the whole of Wales by using 'index species' and the floristic composition of the widely distributed grassland.

It is possible to devise a classification based primarily on existing land use provided that natural, historical and economic factors are all adequately considered. The Land Utilisation Survey has completed a field-to-field survey of present land use over the whole of England, Wales and Scotland. The six-inch field maps and the one-inch coloured maps (of which eighty sheets have now been published) form the starting point for comparison with the past. Over large areas of the country, a direct comparison can be made with the period 1837–1845 by plotting on to modern six-inch maps the information collected in parish surveys made under the Tithe Redemption Act of 1836—a tedious and laborious though illuminating exercise. In some areas, eighteenth century enclosure, manorial and other medieval maps carry

back the story much farther. Contrary to popular belief, the natural factors exercise a greater influence now than they did in the past in the determination of land use. With the improvement of internal communications and the development of overseas supplies, it is no longer economic to use land for the production of commodities (such as wheat in much of the West and Midlands) for which it is, for climatic or edaphic reasons, unsuited.

Most of Britain has been settled and farmed for hundreds, if not thousands, of years. Recent land-use is often the result of a long continued process of determination by trial and error. Our investigations have stressed what might therefore be expected, though which is constantly denied, that there is a remarkable stability of land use in Britain. This applies to the poorest land—moorland and wasteland now and in the past; and to the best land—selected for ploughland in the past and remaining under the plough to the present day despite economic vicissitudes. The maximum of change has taken place on lands of intermediate

quality—under certain economic conditions it may pay to plough them; under others to put them down to grass; under others to abandon them entirely or in part.

Thus the classification of the land of Britain now proposed is based on a variety of considerations. The accompanying map is a first attempt to show the approximate distribution of each type. It has been prepared on incomplete information and is published now for the first time in order to secure constructive criticism.

(1) *Land of the highest agricultural value—actual or potential market-garden land*, capable of intensive cultivation, with deep, fertile, easily worked loamy soils, retentive of moisture and of manure and often naturally rich in humus and mineral salts. Most of this land has long been tilled, though some (for example, Fenland and south Lancashire) has been made available by careful drainage. This is the land above all other needed by the nation for the production of fresh fruit and vegetables, and which needs protection from the inroads of housing and industry. Its protection near towns is especially desirable to secure local supplies of fresh vegetables. Some at least might be reserved for allotment gardens.

(2) *Land of high agricultural value—the major ploughlands*. For climatic reasons this land is mainly in eastern and southern England and is the land from which Britain must obtain the bulk of her ordinary farm crops for direct human consumption. Whilst from its position and character some may be needed for aerodromes and other national requirements, it should be protected so far as possible from housing and industrial development. Most has shown great stability in use as crop land.

(3) *Land of high agricultural value—first quality grassland*. This includes the best 'fattening pastures', capable of fattening one bullock per acre (or equivalent in other animal units) and usually managed as permanent grassland. Soils are often heavy though fertile and surface water is available. The land is the basis of the home-killed beef industry and much of the dairying industry and should be preserved as far as possible.

(4) *Land of high agricultural value—the major stretches of good grassland*. The carrying capacity is lower than on the first quality grassland and the pastures are not normally fattening pastures without the aid of auxiliary feeding stuffs. The land should be regarded as primarily agricultural but not debarred from other uses under adequate safeguards or control.

(5-7) *Lands of intermediate value*. In the present state of information available no attempt has been made on the map to subdivide this land,

though clearly two or three major types can be separated; for example, the broad stretches of downland, normally under mixed farming, contrasting with the hilly lands of western England and Wales under alternate husbandry. Quite apart from detailed soil studies (the soils are extremely varied) most of this land can be detected when its utilization is studied historically. Much of it to-day is under pasture (often of second quality with reeds, rushes, bracken, etc.); in past times of prosperity or under economic stimulus, much of it was ploughed and cropped; with the advent of times of depression, it became in part agriculturally sub-marginal and much is allowed to lie idle. This is land which should be the especial concern of national planning, where an integration of agriculture, housing, industry, including garden cities, recreational areas, high-speed parkways and other requirements of present and future, should really be planned.

(8) *Land of low agricultural value—moorland and rough hill pasture*. This is land with immature mountain soils, usually thin, or stony podsolized soils, which is of limited economic value as rough grazing, as sporting estates or as gathering ground for water supply. Because of its hilly or mountainous character it is rarely suitable for industrial development, but its greater use in the national economy can be found by a careful division into areas suitable for (a) improvement to good pasture, (b) afforestation, (c) recreation (national parks, etc.), (d) water supply and (e) rough pasture as at present.

(9) *Land of low agricultural value—heathland and lowland areas of rough pasture*. These are the old 'wastelands' of the medieval farmer, usually with 'hungry' light soils, and most of the 'commons' of south-eastern England, as well as larger areas such as the New Forest and Breckland, are of this type. Where occurring near towns, this land is ideal for those parts of 'green belts' designed primarily as public open spaces—scenically attractive with heather and pine woods and drying quickly after rain. If abundant (for example, parts of Surrey) the land is very attractive for good types of residences, provided the owner does not look for a substantial return from the cultivation of his garden or small-holding. The more extensive or remote areas are suitable for coniferous afforestation, military training grounds, and even in some areas for industrial purposes.

The driest and least fertile tracts of downland and limestone pasture are allied in value and utilization; for example, parts of the Chilterns and South Downs.

(10) *Land of low agricultural value—rough marsh pasture, saltings, etc.* Although the reclamation of such land often provides good grazing

(Thames marshes) or even good arable land, it is expensive and difficult to justify commercially; on the other hand, the waterside location, ease of excavation for docks, wharves, etc., and the possibility of building up the land by dredging silt from neighbouring watercourses and thus

improving the river channels, makes this cheap land attractive to heavy industry. There is every reason to encourage industry to use such land; for example, Tees-side, Teemouth, Thames-side; banks of Lower Medway, certain parts of Southampton Water, etc.

National Nutrition Policies

By Sir John Boyd Orr, F.R.S.

IT has been known for many years that faulty diet is the direct cause of a heavy mortality throughout the world through deficiency diseases such as pellagra and beriberi, and, even in the wealthiest countries, of a great deal of ill-health. It has also been known that diseases due to faulty diet are possibly the easiest of all to prevent. Yet we are only now beginning to make a survey of the extent of the damage being done to the human race by malnutrition, and of our food resources available to prevent that damage.

Through the action of the League of Nations, this is now being done on an international basis*. Following the recommendation of the League's Mixed Committee on Nutrition, twenty-one countries have set up national nutrition committees to collect information regarding the state of nutrition in the different countries and to ascertain what is needed to make national dietaries fully adequate for health. The committees are conducting inquiries on what foods and what amounts of each are consumed by people of all classes and living under all sorts of conditions. This information, got by family budget inquiries and dietary surveys, enables estimates to be made of the nutritive value of the diet of different classes and also gives an indication of the level of income necessary for adequate nutrition. A parallel investigation of the state of nutrition of the families whose diets are determined will give some indication of the extent to which ill-health and poor physique can be attributed to deficiencies in the diet.

It is difficult, however, to assess the relative influence on health of faulty diet and of other factors inimical to health which usually accompany faulty diet. Useful information on this can be obtained by feeding experiments on children on poor diets, the deficiencies of which are made good by the addition of supplements of high nutritive value, and comparing the subsequent health of these children with that of children on similar diets and under comparable conditions but not receiving supplementary feeding. A further line of inquiry

recommended is a survey of total national food supplies, home products plus imports, and a comparison of total food available with total national nutritional requirements. The information obtained in all these investigations will show what changes are needed in national food policies in the interest of health.

Governments were requested to furnish to the League annual reports on the work of their nutrition committees and the secretariat was instructed to publish an annual summary of these statements and of the proceedings of meetings of the representatives of the national committees. This survey of national nutrition policies now available gives the first annual report on the statements received and of the proceedings of the first meeting held last October, at which sixteen countries were represented.

Though the work of most of these committees is still in the initial stage, this report promises well for the success of the difficult work which they have undertaken. The information brought out in the preliminary inquiries shows the great need for a world-wide investigation and the immense possibilities of promoting human welfare by the application of "the newer knowledge of nutrition". The facts already revealed are sufficiently startling to warrant immediate changes in national food policies. Even in a country like Australia, where the standard of living is high compared with European countries, it was found that clinical survey with modern scientific methods revealed a quite unexpected amount of malnutrition. Of more than three thousand children examined in four inland areas, 17.9 per cent were recorded as showing evidence of unsatisfactory nutrition. An inquiry among pre-school children in Melbourne revealed evidence of malnutrition in 21.7 per cent of those examined. It is suggested that the malnutrition is due to a lack of dairy products, fruit and vegetables. The Australian Government has been trying to find a market for the export of these. It looks as if she has a market within her own borders which could be exploited to the great benefit of the people of Australia. In the United States, more than 60 per cent of the diets of Negro

* League of Nations. *Survey of National Nutrition Policies, 1937-38.* (Official No.: C478.M.321.1938.IIA.) Pp. 120. (Geneva: League of Nations; London: George Allen and Unwin, Ltd., 1938.) 2s. 6d.

families in the south were found to be in need of improvement. In Hungary it was found that if requirements are to be fully met and exports maintained at the present level, milk production would need to be increased by 120 per cent and eggs by 470 per cent. In Jugoslavia, the peasant's winter diet consists almost solely of bread and beans. In summer, it provides nearly all the necessary elements, with the result that, in the autumn, there is a noticeable improvement in nutrition. Under the existing economic conditions, the peasant is obliged to sell his milk and eggs, and farm workers and children suffer from all kinds of deficiency diseases. Rickets and pellagra are specially common. During the Easter fast, epidemics of night-blindness and other eye diseases occur in certain regions. It is stated that some villages observe practically all orthodox fasts, which may amount to as many as 206 in the year.

These are examples of the kind of facts being brought to light by the work of these national nutrition committees. They are dealing with an urgent world-wide problem. They are showing the direction in which modern science can be most easily applied for the promotion of human welfare, pro-

vided Governments can devise ways and means to increase production of the 'protective' foods, to facilitate distribution and adjust the economic system to bring a diet adequate for health within the reach of all and, at the same time, carry on educational campaigns so that families may be able to adjust their expenditure on food to the best advantage.

The work which the League of Nations has done in initiating and carrying on this work for the improvement of nutrition on an international basis is sufficient alone to justify its establishment. The League provides an international organization which can mass the world's scientific knowledge on the problem, and bring together the representatives of all the different countries once a year to get the mutual benefit of the exchange of information and the discussion of difficulties. The enthusiasm for the work would be increased with the knowledge that the information obtained is being used for the evolution of agricultural, trade and economic policies, designed to adjust national food supplies to national requirements and so bring the work of the national committees to full fruition.

Element 43

By Prof. E. Segrè

EVERY time that physics has offered a new analytical tool to chemistry, the most striking success has been the discovery of new elements. Rubidium and caesium are thus offsprings of the use of the spectroscope, polonium and radium were discovered through the new methods of radioactivity, hafnium and rhenium were recognized through their X-ray spectra.

Mendeléeff's work, on the other hand, by classifying the chemical types, has in a way set a limit to the possibility of further discoveries and gives also a method of predicting rather exactly the properties of the missing elements. These are element 43, a lighter homologue of rhenium; element 61, a rare earth; element 87, a halogen; and element 89, an alkali. The search for these elements in the minerals, the only source at our disposal until a few years ago, has not been successful, and none of them seems to have been recognized with certainty in the earth's crust, in spite of considerable effort¹.

Artificial radioactivity has supplied chemistry with a powerful new instrument, and from the point of view of the discovery of new elements its most striking feature is that one is able now to create, by transmutation from other elements, the element one wants to study. The first achieve-

ment in this type of investigation was the discovery of transuranic elements by Fermi and his co-workers, continuing the periodic system above uranium (No. 92), although, in view of recent work, confirmation of their existence is needed.

In the search for the four missing elements lower than uranium, we have now been able to prepare element 43 and study its properties in detail. The substance was produced in the Berkeley cyclotron, which thus remains for the time being the only 'mine' of the element. It was made by bombarding molybdenum with deuterons or with neutrons².

At least five radioactive isotopes of atomic number 43 have been recognized³ among the products of the bombardment, and some of them have a half-life long enough to permit a rather complete investigation of the chemical behaviour of element 43. Actually perusal of the periodic table may help to predict many of its chemical properties but, on the other hand, the finer details, often very important from the analytical point of view, may be found only by direct experiment.

The first properties to be studied obviously should be the analytical ones, in order to be able to identify the new element and separate it from all the others. Many of the separations are quite

elementary and there is no need of any special study to devise them, but for the separation from the neighbouring elements things are more complicated, and emphasis has to be put on the separation from manganese, molybdenum, ruthenium and especially rhenium, which are the four elements closest to element 43 in the periodic table, and have most resemblance to it. The methods and principles of the chemistry of minute amounts of substance and of radioactive detection, as worked out by Curie, Rutherford, Soddy and others in their classical work on the natural radioactive elements, have been employed throughout and satisfactory methods of separation have been worked out. The fundamentals of the analytical chemistry of this element have thus been secured and can now be utilized for further progress.

Practically none of the many physical constants of the new element can be determined using amounts of the order of magnitude of 10^{-10} gm. of substance as produced artificially; but this situation prevails also for some of the natural radioactive substances, and there is at present no possibility of overcoming this difficulty. On the other hand, properties such as the volatility of certain compounds, partition coefficient in frac-

tional crystallization, etc., can be determined even with such tiny amounts of substance, and some of these have actually been measured.

A fortunate circumstance allows us to detect even the K_{α} line of the X-ray spectrum of element 43, though the amount of substance would not be sufficient to show, by ordinary methods of external excitation, this spectral line, or any optical line. One of the radioactive isotopes of 43 exists in two isomeric states and the upper state decays into the lower. By the mechanism of internal conversion of the gamma rays, these transitions eject the K electron of the atom 43, which is now in a condition to emit the characteristic X-ray line. This line has been identified by its absorption discontinuity in neighbouring elements¹, and more recently it has even been possible to photograph it in a bent crystal spectrograph². This is the first time that the X-ray line of a new element, synthesized artificially, has been directly observed.

Obituary Notices

Prof. Henry Louis

THE death of Prof. Henry Louis at his home in Newcastle-upon-Tyne on February 22 at the age of eighty-three years marks the passing of a period in the life of the Royal School of Mines, as he was the last survivor of the students who were present at the first annual dinner held in 1873.

Louis was born in London, and after receiving his preliminary education in London and Germany entered the Royal School of Mines in 1873, where he studied mining under Warrington Smyth and metallurgy under John Percy. He became remarkable for the wide scope of his learning, and won fame as a mining engineer, a metallurgist, a teacher and a linguist.

After graduating first of his year, Louis worked for some time in Percy's laboratories and then commenced his professional work in association with Sir William Siemens. For twenty years he was entirely engaged in reporting upon and managing metalliferous mines in different parts of the world, including South and West Africa, South and North America, Malaya, California and Spain. Thus his knowledge of mining practice became almost encyclopaedic.

During this period, Louis never lost his early interest in primary metallurgy, both ferrous and non-ferrous, so that when he was appointed to the joint posts of professor of mining and William Cochrane lecturer in metallurgy in Durham College of Science, Newcastle-upon-Tyne, now King's College,

Newcastle-upon-Tyne, in 1895, there could have been no more fitting choice. As a teacher he was outstanding. His personality impressed itself on his students and inspired them in a remarkable way, his fund of knowledge and experience being a perpetual source of joy to all those who had the good fortune to work under his direction.

Louis was the author of many publications, in which the breadth of his knowledge is admirably displayed. While he was a persistent and usually kindly critic of the work of his fellows, his comments at times could be devastating. He took a very active part in the life of many professional institutions and was elected president in 1927 of the Institution of Mining Engineers, and in 1929 of the Iron and Steel Institute, which awarded him the Bessemer Gold Medal in 1932. A year later he was elected a fellow of the Imperial College.

The last forty years of Louis' life centred around the northern coalfield, where his work as professor and emeritus professor, as well as his twenty-five years' association as secretary, with the North of England Institute of Mining Engineers will long be remembered. He was a member of various Government Commissions, of which two—the Royal Commission on Mining Subsidence, 1923–1927, and the Commission to inquire into the practicability of gold mining in Merionethshire, 1930—were of particular interest to him.

J. A. S. RIMSON.

Dr. W. E. Grimshaw, O.B.E.

THE Research Department, Woolwich, has suffered a serious loss through the untimely death of Dr. W. E. Grimshaw, deputy director of ballistics research, at the age of fifty-eight years.

Dr. Grimshaw originally joined the department in 1916 as an assistant proof and experimental officer, remaining at Woolwich until September 1919, and then left to resume his pre-War employment as one of His Majesty's inspectors under the Board of Education. He rejoined in 1921 and at once took a leading part in the investigations into fundamental ballistic problems which had, of necessity, to be kept in abeyance during the War period. For this work he was peculiarly fitted as he could combine his wide knowledge of mathematics and physics with the practical artillery experience gained during his War service.

A long series of researches, experimental and theoretical, on the burning of propellants in a closed vessel culminated in the joint publication with Dr. A. D. Crow of two important papers, "The Equation of State of Propellant Gases", (*Phil. Trans. Roy. Soc., A*, 230; 1931) and "The Combustion of Colloidal Propellants" (*Phil. Trans., 230*; 1932). The first paper greatly extended Petavel's early work on the subject (*Phil. Trans. Roy. Soc., A*, 205; 1905) while the second put forward the theory that the rate of burning of a propellant (such as service cordite) is conditioned by the density of the surrounding gases rather than by their pressure (Cf. Mansell, *Phil. Trans. Roy. Soc., A*, 207; 1908). The mathematical consequences of this theory as applied to internal ballistics were examined in two further papers, with Dr. Crow, on "The Combustion Problem of Internal Ballistics" (*Phil. Mag.*, 15, 529, 729; 1933).

Another problem to which Grimshaw turned his attention was that of the behaviour of plastic metals under stress. The determination of the maximum gas pressure in a gun is a matter of great importance for ordnance design, and the service (crusher-gauge) method is to measure the amount of compression experienced by a small copper cylinder enclosed in a steel container fitted with a piston. This gauge, whilst giving reliable comparative results, is known to record less than the true pressure by amounts which vary with the nature of the gun and propellant employed. Grimshaw examined the problem afresh in his paper "The Plastico-Viscous Deformation of Right Circular Cylinders of Soft Metal under Variable Load Axially Directed" (*Phil. Trans. Roy. Soc., A*, 233; 1934), and intended afterwards to make practical use of the theory developed therein. The foregoing papers represent only a portion of his work, as it must be remembered that much of it had, of necessity, to remain secret; but it may be said that there was not one of the many and various problems connected with ballistics to which he did not make some contribution.

Grimshaw's earlier career at Oxford had been a brilliant one. A scholar of Corpus Christi, he took first classes in the Final Honour Schools both of mathematics and of physics, and he was junior and senior mathematical scholar of the University

graduating B.A. in 1904 and M.A. in 1907. The degree of D.Sc. was conferred on him in 1936, and he was a foundation fellow of the Institute of Physics. His duties as an inspector of schools gave him no opportunities for research, but he got his chance in later life, although of recent years the burden of administrative work left him little but his leisure time for investigation. He had a very wide knowledge of modern mathematical physics and kept abreast of the times by incessant reading.

To his younger colleagues, Grimshaw was always generous with encouragement and help, and was consulted by them in any difficulty as a matter of course. He will be greatly missed as a most valuable member of the Research Department, and as a very loyal friend.

C. A. C.

Dr. G. H. Carpenter

THE REV. DR. GEORGE HERBERT CARPENTER died at Guildford, Surrey, on January 22, at the age of seventy-three years. Born at Peckham in 1865, he was the son of George Carpenter and Phoebe Hooper. His early education was private; later he carried on his studies at King's College, London, and at the Royal College of Science, Dublin. After a period as clerk in the Natural History Museum, South Kensington, he became, in 1888, assistant naturalist at the Dublin Museum. He gave up this post in 1904 on being appointed professor of zoology at the Royal College of Science (Dublin), where he stayed until 1922. On leaving Ireland he became keeper of the Manchester Museum (1923-34). A few years after his return to England he became a deacon of the Church and a priest a year later. He was honorary curate at Christ Church, West Didsbury, from 1926 until 1934 and was transferred to a similar position at St. Augustine's, Broxbourne, from 1935 until 1937. He was editor of the *Irish Naturalist* for thirty years, secretary of the Royal Zoological Society of Ireland from 1911 until 1919 and afterwards secretary of the Royal Irish Academy.

Most of Carpenter's published work was in connexion with entomology. Of his books, "Insects, their Structure and Life", first published in 1899, is an admirable elementary manual. This was followed by his "Insect Transformation" (1921) and the "Biology of Insects" (1928), both of which are characterized by accuracy and clearness of exposition. He made a special study of the order Collembola and became the leading authority on this group in Great Britain. On the morphological side, he was specially interested in segmentation among arthropods and wrote several papers on this topic which were noteworthy in their day. For a number of years, he was consulting entomologist to the Royal Dublin Society, and in this capacity wrote a series of reports on injurious insects in Ireland. He was especially interested in the warble fly problem, and on this subject he contributed valuable papers based on carefully planned experiments.

Carpenter's death removes from our midst a kindly and generous personality. He is survived by his wife and son.

A. D. I.

Dean L. P. Reinhold Matsson

THE death last summer of Dean Reinhold Matsson, botanist, geneticist and churchman, at the relatively early age of sixty-eight years, is a distinct loss to rhodology and systematic botany in Europe.

Since the time of Linnæus, there has been a traditional line of systematic botanists in Sweden—Afzelius, Swartz, Hartman, Wahlenberg, Fries, Scheutz, Winslow, Almquist and Matsson—who have worthily upheld the torch first lighted by the Swedish father of systematic botany. The last two, Sigfrid Almquist and Dean Matsson, both specialized in the genus *Rosa*, and although their methods were so original and diverse from one another, their results were complementary.

Dean Matsson had the good fortune to be born on the famous island of Gotland and to attend school in the medieval town of Visby, well known as the 'city of ruins and roses'. The abundance of wild and naturalized roses in the district no doubt attracted the natural curiosity of a born researcher like Matsson who, though destined for the church, was by nature a naturalist and man of science. At the University of Uppsala he happily combined the studies of theology and botany, and at an early age, under the direction and supervision of the world-famous Belgian rhodologist, Prof. Crepin, he made a thorough study of the genus *Rosa* and afterwards continued his researches on his own original lines. His first scientific paper was published in 1895 after two years' research in Gotland, Öland and Småland, followed by papers in 1900 and 1901.

In the latter year, Matsson achieved a European reputation by his conspectus of *Rosa* in Neuman and Ahlfvengrens' 'Flora of Sweden'. Further contributions appeared in 1912, 1915 and 1916, culminating in his *magnum opus* of 1934–35, 'Examen Rosarum Suecicæ', published in *Kungl. Svenska Vetenskapsakademiens Handlingar*, 14, No. 3, pp. 1–380 (1934), Stockholm. In the course of his numerous collections, Matsson accumulated an extensive herbarium of valuable rose material. Like all practical botanists, Matsson was an enthusiastic gardener and geneticist, and in his gardens at Hudiksvall, in the Province of Hälsingland, he cultivated and experimented genetically with the forms of *Rosa* collected in his expeditions. In 1912, his remarkable genetical experiments in breeding various species of Canine true to type, after the flowers had been carefully castrated, demonstrated, for the first time on a large scale, the existence of apomixis in the Canine roses. This important fact, since confirmed genetically and cytologically, has led to the generally accepted theory of the hybrid origin of all the Canine species of *Rosa*.

Matsson also gave considerable assistance to Tackholm in identifying the material used by him in his important work on the chromosomes of *Rosa*, and he was fully alive to the advantages of combining genetical with systematic work.

As a systematic botanist, Matsson was more analytical than synthetical, and the permanent value of his systematic work lies in his minute and accurate

analyses of the character-combinations of the multitudinous forms, varieties, subspecies, and natural hybrids of the Canine species of *Rosa*.

O. C. HURST.

Mr. C. H. Jenkinson

MUCH of the success of modern experimental research depends upon the quality of the instruments that are available, and it often happens that in the apportionment of credit for work done, the share of the workshop is comparable with that of the laboratory. Mr. C. H. Jenkinson, who died on March 6 after a short illness, was one of those artistic instrument-makers to whom science is in debt. He was trained in the works of the Cambridge Scientific Instrument Co. Nearly thirty years ago, he was given charge of the physics workshop of the University of Leeds. He made the first X-ray spectrometer. As the X-ray analysis of crystal structure developed and greater demands were made upon his skill, he never failed to respond, and to better the instructions given to him. Researches in various branches of physics, carried out at Leeds, at University College, London, and finally at the Royal Institution were greatly facilitated by his ingenuity in design, his judgment of material and his beautiful technique. In the reconstruction of the Royal Institution buildings his advice was of material value. He acted as a judge at the Physical Society's exhibitions in recent years. He will be sadly missed by the staff of the Davy Faraday Laboratory, and by all who are responsible for the effectiveness of the Royal Institution.

W. H. B.

We regret to announce the following deaths:

Prof. Giuseppe Cesàro, formerly professor of mineralogy in the University of Liège, a past-president of the Belgian Academy of Sciences and *correspondant* for the Section of Mineralogy of the Paris Academy of Sciences.

Prof. H. M. Dawson, F.R.S., professor of physical chemistry in the University of Leeds, on March 11, aged sixty-three years.

Marcel Godchaux, professor of chemistry and doyen of the Faculty of Sciences of the University of Montpellier and *correspondant* for the Section of Chemistry of the Paris Academy of Sciences, known for his work on the heterocyclic carbon compounds, on February 11, aged fifty-nine years.

Prof. A. M. Hocart, professor of social anthropology in the University of Cairo, on March 9, aged fifty-five years.

Dr. Ivan C. Jagger, senior pathologist in the Bureau of Plant Industry, U.S. Department of Agriculture, on February 16, aged forty-nine years.

Prof. C. M. Jessop, emeritus professor of mathematics in the University of Durham, on March 9, aged seventy-six years.

Prof. E. B. Wilson, For. Mem. R. S., Da Costa emeritus professor of zoology in Columbia University, on March 3, aged eighty-three years.

News and Views

Discovery of a Living Crossopterygian Fish

THE discovery of a living crossopterygian fish of the order Actinistia, described and illustrated on p. 455, is an event of outstanding importance. There can be no doubt that Dr. J. L. B. Smith, who is to describe this specimen, is correct in placing it in the family Coelacanthidae, of which it would appear to be a typical member. In some respects, the present specimen seems to bear a closer resemblance to genera of the early Mesozoic era such as *Undina* than to the later coelacanths of the *Macropoma* type from the Upper Cretaceous. The fact that no traces of fossils referable to this family have been found in rocks later than those of the Cretaceous period makes the discovery of a living representative in South African seas even more remarkable. It is stated that the skeleton of the living fish was found to be cartilaginous and the vertebral column apparently tubular. In the fossils the central part of the vertebral column has disappeared, and was probably cartilaginous, but the neural and haemal spines were ossified. A unique feature of the fossil coelacanths is the ossified air-bladder, which can be seen clearly in many specimens, and it will be of interest to learn whether this character was observed in the living fish. The photograph of the South African fish seems to show paired nostrils just in front of the eye; but this is another feature of which we must await confirmation. Dr. Smith's detailed report will be awaited with great interest by zoologists and paleontologists alike, and it is little short of a tragedy that the unfortunate disposal of the body of the fish after skinning will make this report very far from complete. An article relating to the discovery of this fish by Dr. E. I. White, of the British Museum (Natural History), accompanied by a large photograph, appeared in the *Illustrated London News* of March 11.

Prof. J. L. Myres, O.B.E., F.B.A.

ON October 1 of this year, Prof. John Linton Myres, Wykeham professor of ancient history in the University of Oxford, will retire, and will be succeeded by Mr. Henry Theodore Wade-Gery, fellow of Wadham College, Oxford. Prof. Myres has occupied this chair since its inauguration in 1910, returning to his own University after three years as Gladstone professor of Greek and lecturer in ancient geography in the University of Liverpool—a chair which also he was the first to hold. His tenure of the Wykeham professorship had already expired under the age limit, but was extended for a further period of five years. His appointment to this chair, which his pre-eminence as a research worker and original thinker in the field of the ancient history (or as it would now be termed the pre- and proto-history) and geography of the Mediterranean region had made almost inevitable, was otherwise appropriate in that he was both a Wykehamist and a member of New College.

BEFORE his appointment to the Gladstone chair at Liverpool, Prof. Myres had been a student of the British School of Archaeology at Athens and had held a fellowship at Magdalen College and a studentship at Christchurch, Oxford; and he had travelled widely and excavated in various parts of the Mediterranean, Greece and the Aegean, Cyprus, Crete, northern Africa and Asia Minor—activities which have continued to occupy much of his periods of vacation. Apart from his reputation as archaeologist, geographer, and historian—many of his discoveries and conclusions are classics of reference—Prof. Myres is known throughout the scientific world for his energy and abilities as an organizer. There are few fields in the economy of science in which he has not intervened to the advantage of men of science and their work. It was during his tenure of office as general secretary of the British Association in the years succeeding the Great War that the organization and working methods of that body were reformed and brought up to date, mainly on his initiative, with the co-operation of the late Prof. H. H. Turner and later of Sir Frank Smith, his fellow secretaries. During the War, Prof. Myres served in the Naval Intelligence in the eastern Mediterranean, where he combined the duties of an intelligence officer with more aggressive tactics, modelled, it was said, on the raids of Homeric heroes. For his services he received the O.B.E. and the Order of King George I of Greece.

Early Civilization and Cultural Relations in Cilicia

EXCAVATIONS at Mersin in Cilicia by the Neilson Expedition to the Near East of the University of Liverpool during the present season have more than justified the anticipation of last year that this site would afford evidence of settlement and early cultural development equal in antiquity to, if not surpassing, anything yet recorded in the Mesopotamian region. According to Prof. Garstang's preliminary report on this season's work (*The Times*, March 10), the sixteenth level of excavation has been found to contain the well-preserved remains of a fortified city—a whole group of great buildings laid out with plan and purpose. This level lies twenty feet below the imperial Hittite fortress uncovered last year; and in it chalcolithic deposits lie beneath a stratified series of building levels, in which the culture is related to the early predynastic Mesopotamian cultures of Uruk and Tell Ubaid. The cultural affinity with predynastic Mesopotamia of the sixteenth level itself is demonstrated by evidence of direct contact with the polychrome phase of the still older Tell Halaf culture. Prof. Garstang's approximate dating assigning this cultural level at Mersin to 3600 B.C. is therefore to be regarded as by no means excessively high; while the line of fortifications with its abutting 'married quarters', and the chief's residence, all brick-built and not of stone, it is to be noted, thus constitute the oldest known example of architecture.

THIS level of chalcolithic occupation, however, lies at a depth of no more than 35 ft. from the summit of a mound which rises to a height of 80 ft. above water level; and it is known that there is a further ten feet of chalcolithic deposits below it before the neolithic strata are attained. In these, the accumulated relics of the original neolithic settlers extend downward for more than 30 ft. Here, Mr. Miles Burkitt, whose expert examination has been invoked, has found evidence, extending from below the painted pottery down to the 12 ft. level, of two main phases of neolithic culture, in which black or brown pottery is associated with tools of obsidian. To the beginning of the later of these two phases he assigns an antiquity which "can hardly be later than 5000 B.C., while the lowest level reached must date a thousand years earlier". As Prof. Garstang points out, the elaboration of the fortifications and dwelling site point to a well-advanced and highly organized existence at Mersin when Egypt, Babylonia, Crete and Europe were still in infancy. Impressive as the chronological range of this Cilician culture must appear to be, its significance for the archaeologist is enhanced, when Prof. Garstang finds in certain details of his ceramic material evidence which appears to point not only to the East, but also to the West, forming a possible link with the Danubian area. Should further examination endorse this suggestion, Mersin will afford something approaching decisive evidence on a crucial problem of European prehistoric chronology of late much under discussion.

Exhibition of Cypriote Antiquities

AN exhibition of pottery of the Early Bronze Age at the Institute of Archaeology of the University of London was opened by the Earl of Athlone, Chancellor of the University, on March 10. This pottery was excavated at Vounous in Cyprus by an expedition sponsored by the British School of Archaeology at Athens and under the direction of Mr. James Stewart. The exhibition, as was pointed out by the Chancellor in declaring it open, is the first to be held in England of the results of an important excavation of purely British origin in Cyprus; and this fact is indeed of special significance in view of the attempts which have been, and are being, made to arouse interest in Great Britain in the early history and antiquities of Cyprus. The cost of the excavation was defrayed by subscription, among the principal subscribers being the University of Cambridge, Sir Charles Hyde, and Sir Charles Marston. The last-named has presented the main part of the finds allotted to him to the Institute of Archaeology, and they form the nucleus of the present exhibition with supplementary loans from the Fitzwilliam Museum, Cambridge, and the Birmingham City Museum and Art Gallery. After the exhibition had been declared open Mr. Stewart gave an account of the site and its excavation. The Vounous site is a cemetery on the east and north sides of a low hill in the foothills of the Kyrenia Mountains. The north side had already been excavated by Dr. Dikaios, and the present work was confined to the east side. The tombs are open caves approached from a forecourt. Burial is in a contracted position, with burial gifts

of pottery and food. The entrance was sealed with a single stone and covered in. Sometimes graves had been opened by an iron age grave-digger, who had again sealed the tomb after inserting a votive offering, with, as Mr. Stewart said, "confusing effect". The chronology of the site falls into three periods, dated tentatively from 2900-2500 B.C., 2500-2300 B.C. and 2300-2050 B.C.

Approach to the Absolute Zero

THE second Poynting Memorial Lecture in the University of Birmingham was delivered by Dr. H. B. G. Casimir, of Leyden, on March 7, on "The approach to the absolute zero of temperature and some properties of matter at the lowest temperatures at present attainable". Dr. Casimir remarked that the subject, being one in which the combination of the theoretical and experimental had been so fruitful, was an appropriate one with which to commemorate a man who had in himself so remarkably embodied this combination. The definition of temperature in terms of an ideal gas enables us to say that the ice-point is 273.15° K., but in practice the gas scale cannot be used directly below 1° K., for at such temperatures gases cease to exist. It is possible, however, by other methods, for example, the resistance of phosphor bronze, to extrapolate to 0.2° K., and very small temperature changes can be measured by using the magnetic properties of substances, so that measurements down to a few hundredths of a degree absolute or even less can be made with a good deal of confidence. Methods of experimenting were explained and the remarkable properties of helium II were described.

It appears likely that it is impossible to solidify helium II, because the solid state requires stability of lattice, and if the helium atom cannot have less energy than $h\nu/2$, this may be sufficient to prevent the formation of a stable lattice no matter how low the temperature. Some special advantages of working at low temperatures were mentioned: Electric insulation is enormously improved; exceedingly high vacua can be attained—if care is taken to exclude helium, vacua down to 10^{-10} or perhaps 10^{-12} mm. of mercury can be attained. Thermal insulation is greatly improved by the almost complete absence of radiation and of gas. Calorimetry is rendered relatively easy, for heat capacities are small, whereas by using the magnetic properties of a salt such as $\text{KCr}(\text{SO}_4)_3 \cdot 12\text{H}_2\text{O}$, temperature changes of the order of 0.001° can be measured, so that the surprising conclusion emerges that the heat generated by allowing a mass of 1 gm. to fall through 0.01 mm. would be capable of detection. The facts of superconductivity suggest the possibility of construction of galvanometers of prodigious sensitiveness and there would be no Brownian motion to cause trouble.

Necker's Map of Scotland

THE first geological map of Scotland, made by Louis Albert Necker in the year 1803, was exhibited by Mr. V. A. Eyles, of the Geological Survey, at a meeting

of the Edinburgh Geological Society on March 9. The map, which belongs to the Geological Society of London, is based in part on information supplied to Necker by other geologists and in part on his own extensive travels in Scotland. The map has never been published, and in view of its historical importance, it is hoped to reproduce a colour facsimile. Mr. Eyles said that Necker, who was born in Switzerland, went to Edinburgh in 1808, and studied geology under Prof. Jameson at the University. He was a grandson of de Saussure, the famous Alpinist and geologist; he was related to Madame de Stael, the novelist, and to Necker, the financier, a minister of Louis XVI. After leaving Edinburgh in 1808, he became professor of mineralogy at Geneva, and travelled extensively in Europe. In 1821, he published an account of his travels in Scotland in a three-volume work entitled "*Voyage en Ecosse et aux Iles hébrides*". He returned to Edinburgh on several occasions. In 1841 he retired to Skye for reasons of health, and remained there until his death in 1861. He was buried at Portree.

Comfort in Travel

At the annual joint meeting of engineering and technical societies organized by the Institution of Automobile Engineers and held on March 10 at the Institution of Civil Engineers, three short papers were read on "Comfort in Travel". The first paper was on road travel by S. Garcke, the second on rail travel by Lord Stamp, and the third on air travel by Capt. E. W. Percival. Mr. Garcke pointed out that much of the improvement in the comfort in travel by road is due to the improvements of the surface of the roads. The invention of the railway was essentially the product of necessity, and was mainly due to finding something better than the water-bound flint or stone road. It seems improbable that further marked improvements in road surfaces can be anticipated. The discomfort due to nervous reaction imposed upon a driver by the presence on the road not only of many signals, but also of advertisements, lights and other contrivances, readily confused with official signs, is very real. Such signs are now greatly on the increase and will have to be controlled.

LORD STAMP laid stress on two elements in rail travel: mental ease and physical ease. Mental ease is promoted by removing difficulties in the way of finding out how to go and when to go. Throughout the United States and Canada many agencies have been established by the British railways, all with the object of easing matters for the customers. Physical ease is promoted by absence of disturbing vibration and noise and by the provision of adequate heating, ventilation and lighting. The L.M.S. Co. has employed eminent men of science in Great Britain to solve some of their problems, and both here and in the United States the motion of tyres of different profiles have been studied by means of cinematograph records. It has been found that a profile as nearly cylindrical as possible gives the greatest freedom from high-frequency lateral oscillations.

Captain Percival considers that the development of the aeroplane has progressed more rapidly than that of any other form of transport vehicle. For very large cities it will soon be essential to have several main aerodromes so as to take care of the ever-increasing traffic.

Social Survey of Bristol

A PRELIMINARY report on the standard of living in Bristol, by H. Tout, has been issued by the University of Bristol Social Survey, of which Mr. Tout is director ("The Standard of Living in Bristol: a Preliminary Report of the Work of the University of Bristol Social Survey." By Herbert Tout. Pp. 64. Bristol and London: J. W. Arrowsmith, Ltd., 1938. 1s. net). The comprehensive social survey of Bristol which is nearing completion has been made possible by the Colston Research Society, which has assumed entire financial responsibility, while the University undertook responsibility for the conduct of the research work and the appointment of the Survey staff. The preliminary report is only concerned with incomes which fall below middle-class levels, and covers four fifths of all Bristol families. The report indicates that, on the whole, the typical Bristol family is fortunately placed and probably better off than the families of many other towns. There are estimated to be 12,000 families in the Survey area which are very comfortable by the prevailing standards, which are not high, in the classes covered. At the other end of the scale there are 11,000 families in poverty. Between these extremes there are 58,000 families whose standard of living calls for no special remark, and some of these have a small margin for saving or pleasure. Beneath them come 21,000 families who, whilst not in poverty, have a hard struggle and whose lot is far from comfortable. Probably 40,000 people in the area live in actual poverty, and among them a disproportionate number of children, so that one out of five working-class children comes from a home that is unable to give it a fair start in life.

THE inquiry upon which the report is based was conducted from May to October 1937, coinciding roughly with the peak of the revival of business which started in 1932. The standard of minimum needs adopted in the survey in assessing poverty closely follows that used by Mr. R. F. George (*J. Roy. Statistical Soc.*, 100, 74 (1); 1937). The average Bristol working-class family has a standard of living more than 100 per cent above its minimum needs, and the average size of the family is only slightly above that of the middle class (3.73 in the poorest groups as against 2.94 in the most comfortable group). The rate of poverty is highest for those under fifteen and lowest for those in their twenties, being only 4.1 per cent in the age group 20-24. Unemployment is outstandingly the most important reason for family income falling below 'needs', and affects nearly one third of the families. Old age ranks third in importance, rather less than one sixth of the cases being assigned to it. Broken families, in which there is no adult male earner, account for 10 per cent of

the cases and sickness for 9 per cent. Insufficient wages account for 21.3 per cent of all families below the standard.

British Chemical Plant

THE reference in the leading article in *NATURE* of January 28 to the report of the Association of Scientific Workers, and more particularly to the urgent need for more State assistance for fundamental research, receives further emphasis from a recent discussion by the British Chemical Plant Manufacturers Association, following an earlier meeting in May 1938. In the report above-mentioned it was specifically indicated that among the more urgent and important cases where State support is required is that of chemical engineering, notably in connexion with raw materials and unit operations. Although the discussions of the B.C.P.M.A. were at first intended to be limited to the question of closer collaboration between chemical manufacturers, chemical plant manufacturers and consultants, with the view of quoting for and providing complete process units, it soon became evident that the scope of debate would have to be extended to include co-operation on much wider grounds, including not only fundamental scientific research but also the economic question of meeting foreign competition effectively. It was not easy to come to any definite decision or formulate a constructive policy of basic research: this is a matter for further discussion between the main sections of the chemical industry and the Government. When one considers, however, the strenuous and for the most part successful efforts of recent years to place chemical engineering in Great Britain on a sounder basis, it is to be hoped that the matter will not be left where it is, in view of its supreme importance in regard to national well-being, export trade and defence.

ON the question of more effectively meeting foreign competition, some plant manufacturers find that there appears to be a tendency both on the part of certain Government departments and of some of the chemical manufacturers to assume too readily and complacently that the British makers of chemical plant and apparatus are sometimes unable or unwilling to tender for complete process units, especially in connexion with new processes; and that this assumption has apparently formed the ground, or one of the grounds, for applications for licence to import foreign plant. The real truth, as was clearly shown at the last informal discussion of the British Chemical Plant Manufacturers Association, is that the need for these complete tenders from one firm is more infrequent than commonly supposed, and that, when it really does arise, the British manufacturer of plant is quite as well able as his foreign competitor to supply complete tenders if the inquiries are genuine and are accompanied by full details and complete designs. The allegation therefore that, whilst German or American firms will supply complete specifications and prices for the whole plant, it is necessary to apply to several different British firms for the various parts, with

consequent greater delay, inconvenience, and enhanced cost, is not quite fair. Nevertheless the fact remains that much foreign plant has been and is still being imported. In addition to this discouragement, the British maker has to face ruthless Government-subsidized competition in foreign markets, and should therefore receive the greater support from his colleagues in the chemical industry and from the Government at home.

Some Earthquakes Registered in 1937

WE have received from Dr. W. Hiller the data concerning earthquakes registered at Stuttgart, Ravensberg and Meestetten-Ebingen in 1937. Stuttgart is now equipped with three Galitzin-Wilip seismographs orientated north-south, east-west, and vertical, one Wiechert vertical seismograph of mass 1,320 kgm., two Mainka seismographs of mass 450 kgm. set north-south and east-west, a seismograph of mass 80 kgm. orientated east-west and a horizontal Wiechert instrument of mass 17,000 kgm. Ravensberg has two Mainka pendulums of mass 450 kgm. orientated north-south and east-west, and two Conrad seismographs of 23 kgm. also set north-south and east-west. Meestetten-Ebingen is equipped with one vertical Wiechert instrument of mass 80 kgm., and two horizontal pendulums of mass 80 kgm. orientated north-south and east-west. The full list of constants for all these instruments is given. The main part of the report concerns the 428 earthquakes registered at these stations during 1937. For each shock recorded a full list of readings, including date, registering station, component, phase, arrival time, period, amplitude in μ , and remarks chiefly concerning the epicentre and epicentral distance from the station, is given. Lastly, there follow two valuable additions to the compilation. First comes a tabulation of microseisms registered on the Galitzin-Wilip seismometers at Stuttgart, including the period and amplitude in μ on the three components, and secondly a careful study of the Hohenzollernalb earthquake of June 17, 1937. The epicentre of this is found to be $48^{\circ} 15.3' N.$, $9^{\circ} 12.4' E.$, ± 2.3 km., depth of focus 19-20 km. $\pm$ about 4 km., and T , 9 h. 56 m. 41.8 s. ± 0.3 s. The publication forms a very valuable addition to the data and literature of seismology.

'Commercial' Water Culture of Plants

AN amusing example of the way in which the publicity of the Press may embarrass scientific workers is provided by the need for Circular 347 of the Agricultural Experiment Station, Berkeley, California, in which D. R. Hoagland and D. I. Arnon have to try to dispel illusions about the commercial possibilities of growing plants by water culture. The authors point out that the technique of water culture contains nothing new and has indeed been employed for more than a quarter of a century by this experiment station, whilst the method was, of course, described by the German physiologist Sachs in his text-book about 1860. The California Experiment Station must rue the day that Dr. W. F. Gericke conceived the idea that the method might have some

commercial application. A Sunday supplement article pictured a housewife opening a small closet off the kitchen and picking tomatoes from vines growing in water culture with the aid of electric lights, whilst a large chain of restaurants in New York City were credited with growing their own vegetables in basements. Actually, as the authors of this circular make clear, whilst very good yields may be obtained under glass from many crops grown in water cultures, with equal attention, similar or better crops may be grown in soil by methods which are more familiar to the amateur and professional grower.

Foam on the Dead Sea

A PECULIAR phenomenon often to be seen on the northern waters of the Dead Sea is that of arcs of foam, more or less semicircular, spreading out fan-wise from certain points of the west and east shores. The arcs seem to spread from the shores in early morning and often meet and even cross during the forenoon. These lines of foam often bear reeds and other vegetation debris that have reached the Dead Sea by inflowing rivers, and, at the seasons of migration, the foam may attract flocks of birds searching for food. Dr. D. Ashbel has recorded some of his observations on this phenomenon and offers an explanation (*Geog. Rev.*, Jan. 1938). The arcs originate from springs on the two shores, and they make discontinuities between bodies of water of different salinity and density. When the outflow of the springs is strong, the arc is frequently not smooth but zig-zag. This explanation contradicts the earlier one of Blanckenhorn that the lines of foam originate from warm water arising along lines of fault on the sea floor. That suggestion does not explain lack of replacement of the lines as each moves forward, which Dr. Ashbel thinks is due to the gentle winds that frequently blow from the land on to the sea during the night and early morning. These winds do not ruffle the water and so mixing does not occur. Gusty west winds such as often occur in the afternoon cause mixing and so the lines of discontinuity disappear.

The Imperial College of Tropical Agriculture

THE Imperial College of Tropical Agriculture in Trinidad is now the recognized centre for post-graduate training in tropical agriculture for the agricultural services of the Colonial Empire. The governing body in its latest report for the year ending August 31, 1938, record that 159 past students of the College have been appointed to the Colonial Agricultural Service and allied services, posts being now held in thirty different parts of the British Empire. The year under review was marked by the retirement of Sir Geoffrey Evans, who had filled the office of principal with much distinction since 1926, and who left the College with its function in the development of agriculture throughout the Colonial Empire firmly established, and with an international reputation as a centre of education and research. Mr. Odin Tom Faulkner, lately director of agriculture

in the Straits Settlements and adviser on agriculture in the Malay States, was appointed to succeed Sir Geoffrey Evans. During 1937-38 the work of the College proceeded on normal lines. Research was mainly concerned with problems relating to cacao, sugar, bananas and citrus fruits, and the cost of much of the work was met by contributions from firms connected with the appropriate industry. The governing body is anxious to raise a substantial endowment fund; but its hope that the grant of £32,000 made by the Carnegie Corporation in 1932 towards this object would be followed by contributions from British firms and others interested in tropical agriculture has yet to be realized. Capital is also required for the purchase of more land for the college farm, for additional laboratories and the reconstruction of the biological building.

The British Association: Engineering Section

AT the Dundee meeting of the British Association, 1939, the Engineering Section proposes to repeat the arrangement which proved so satisfactory during the meeting in Cambridge last year and to devote some time to the delivery of a number of short communications by junior engineers or research workers (under the age of thirty years). Each speaker will be allotted a total of 20-30 minutes, which may, at his option, include, say, ten minutes for very short discussion. It is hoped that each author will describe some item of special interest or novelty upon which he may be engaged. This innovation seems to us important as enabling the Association to know something of the work of younger men, and enabling those men to gain experience of summarizing their work and putting it forward for criticism without having to undertake the much more laborious task of preparing a paper of the stature necessary for a full meeting of one of the engineering institutions or of a scientific society. Although *Engineering* publishes *in extenso* the text of all main papers delivered to the Section, it is not proposed that these short papers should similarly be published. This arrangement seems desirable, partly because authors may be prepared to describe engineering work upon which they hope later to publish a full-scale paper, and partly because authors may not feel justified in preparing a text of the completeness which would be desirable if proper publication is to be made. Those wishing to submit such papers should communicate immediately with the recorder Wing-Commander T. R. Cave-Brown-Cave, University College, Southampton.

Spectrochimica Acta

THE first number of a publication under the above title will shortly be issued by Messrs. Julius Springer, Berlin, under the editorship of W. Gerlach and G. Scheibe, Munich; A. Gatterer, Vatican Observatory; R. Breakpot, Louvain; F. Twyman, London. It will deal solely with spectrochemical analysis, and a useful feature will be the publication of abstracts and reviews of books and articles on the subject. A number of authorities on the subject have agreed to collaborate, and those in the English-speaking

countries who have already consented to act in that capacity include Prof. A. Fowler, Prof. H. Dingle and Dr. S. Judd Lewis of London; and Prof. O. S. Duffendack, Prof. J. A. Harrison and Dr. Lester W. Strock of the United States. The first number of the journal will probably be published in May. The English editor will be pleased to receive papers in English on the subject, which should be addressed to: The Editor, *Spectrochimica Acta*, 98 St. Pancras Way, London. N.W.1.

University Co-operation

THE recently published report of the Executive Council of the Universities Bureau of the British Empire announces preliminary steps towards bringing about an informal conference between some of the heads of universities in the United States of America and those of universities in the British Empire. In the course of a trans-Atlantic tour undertaken last spring, primarily with the object of cultivating helpful relations with the Canadian universities, the secretary of the Bureau got into touch with the presidents of Harvard and Yale, the president of the Carnegie Corporation of New York and the director of the Institute of International Education, and discussed with them the possibility of a visit to England of some of the heads of universities in the United States in 1941, when the sixth quinquennial congress of the Universities of the British Empire will be held in Manchester.

Announcements

THE Secretary of State for Air, Sir Kingsley Wood, on the recommendation of the Director of Medical Services, Royal Air Force, has appointed the following standing committee to investigate and advise him on the medical aspects of all matters concerning personnel which might affect safety and efficiency in flying: Sir Edward Mellanby (chairman), Prof. F. O. Bartlett, Mr. E. A. Carmichael, Mr. C. S. Hallpike, Dr. B. H. C. Matthews, Sir John Parsons and Prof. L. J. Witts. The representatives of the Air Ministry on the Committee will be Air Vice-Marshal A. V. J. Richardson, director of Medical Services, and Air Commodore H. E. Whittingham.

THE following have been elected officers of the Physical Society for the year ending March 1940: *President*, Prof. Allan Ferguson; *Vice-Presidents*, Prof. G. I. Finch, Dr. Exer Griffiths, Dr. L. Hartshorn, Mr. R. W. Paul; *Hon. Secretaries*, Mr. J. H. Awbery, Dr. W. Jevons; *Hon. Foreign Secretary*, Prof. O. W. Richardson; *Hon. Treasurer*, Dr. O. C. Paterson; *Hon. Librarian*, Dr. J. H. Brinkworth.

THE following have been elected officers of the Geological Society of London for the ensuing year: *President*, Prof. H. H. Swinnerton; *Vice-Presidents*, Dr. E. B. Bailey, Prof. W. G. Fearnside, Prof. O. T. Jones, and Prof. C. E. Tilley; *Secretaries*, Dr. L. Hawkes and Prof. W. B. R. King; *Foreign Secretary*, Sir Arthur Smith Woodward; *Treasurer*, Mr. F. N. Ashcroft.

THE following have been elected officers of the Quekett Microscopical Club for the ensuing year: *President*, W. E. Watson Baker; *Vice-Presidents*, H. G. Brown, C. H. Caffyn, D. J. Scourfield, P. K. Sartory; *Hon. Treasurer*, Dr. C. L. Odam; *Secretary*, Miss C. Arnold; *Reporter*, A. Morley Jones; *Curator*, C. J. Sidwell; *Assistant Curator*, W. F. Reeve; *Librarian*, H. C. G. Best; *Editor*, W. P. Sollis.

THE following appointments and promotions have recently been made in the Colonial Service: A. J. Hans, veterinary officer, Kenya; Dr. S. E. Piercy, veterinary research officer, Kenya; Dr. R. B. McConnell, assistant field geologist, Tanganyika Territory; P. A. Loixides, agricultural chemist, Cyprus; R. J. Lathbury, senior plant breeder, Agricultural Department, Kenya; R. G. H. Wilshaw, senior chemist (soils), Malayan Agricultural Service; H. G. Pudney, senior inspector of produce, Agricultural Department, Nigeria.

THE Leslie Dana Gold Medal awarded annually by the Association for Research in Ophthalmology and the St. Louis Society for the Blind was recently presented to Prof. Ellice M. Alger for his contributions to ophthalmology during the last thirty years and his work as a teacher. For many years he had been professor of clinical ophthalmology at the New York Postgraduate Medical School.

A CONFERENCE and working demonstration on "Pure Fruit Juices and Syrup" will be held at the Long Ashton Research Station of the Department of Agriculture and Horticulture, University of Bristol, on March 23. Further information can be obtained from the Director, Research Station, Long Ashton, near Bristol.

THE French Association for the Advancement of Science will meet this year at Liège on July 17-22, under the presidency of Prof. O. Fabry, director of the Optical Institute, Paris. The local committee for the meeting is under the chairmanship of Prof. Dehali, of the University of Liège.

A FLEMISH Academy of Medicine, consisting of six sections, has recently been founded at Brussels.

THE fifth International Congress for First Aid will be held at Zurich and St. Moritz on July 23-28.

THE eighteenth Congress of the German Association for Microbiology will be held in Vienna on March 27-30. Further information can be obtained from the Secretary, Prof. Wohlfeil, Führerstrasse 2, Berlin, N.15.

REPRESENTATIVES of thirty-five countries will attend the tenth International Congress of Military Medicine and Pharmacy, which is to be held at Washington on May 7-15. Further information can be obtained from the Secretary-General of the Congress, Army Medical Library, Washington, D.C.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 478.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Liberation of Neutrons in the Nuclear Explosion of Uranium

RECENT experiments^{1,2} have revealed the existence of a new kind of nuclear reaction: neutron bombardment of uranium and thorium leads to an explosion of the nucleus, which splits up into particles of inferior charge and weight, a considerable amount of energy being liberated in this process. Assuming a partition into two particles only, so that the nuclear mass and charge of uranium have to be distributed between two lighter nuclei, the latter contain considerably more neutrons than the heaviest stable isotopes with the same nuclear charges. (A splitting into, for example, ⁹²Rb and ¹⁴¹Ce means an excess of 11 neutrons in the first, and of 8 neutrons in the second of these two nuclei.) There seem to be two possibilities of getting rid of this neutron excess. By the emission of a β -ray, a neutron is transformed into a proton, thus reducing the neutron excess by two units; in the example given above, five and four successive β -activities respectively would be needed to restore the neutron-proton stability ratio. In fact, the explosion products have been observed to be β -active and several periods have been recorded, so that a part, at least, of the neutron excess is certainly disposed of in this way. Another possible process is the direct liberation of neutrons, taking place either as a part of the explosion itself, or as an 'evaporation' from the resulting nuclei which would be formed in an excited state.

In order to find some evidence of this second phenomenon, we studied the density distribution of the thermal neutrons produced by the slowing down of photo-neutrons from a Ra- γ -Be source in a 1.6 molar solution of uranyl nitrate and in a 1.6 molar solution of ammonium nitrate (the hydrogen contents of these two solutions differ by only 2 per cent). Plotting $I\tau^2$ as a function of r (where r is the distance between the source and a given point, and I is the local density of thermal neutrons at the same point, measured by the activity induced in a dysprosium detector), a curve is obtained the area of which is proportional to $Q\tau$, Q being the number of neutrons per second emitted by the source or formed in the solution and τ the mean time a neutron spends in the solution before being captured^{3,4}. Any additional nuclei, which do not produce neutrons, brought into the solution, will increase the chances of capture and therefore decrease τ and the area. If, however, these dissolved nuclei are neutron-producing, Q will be greater and the area of the curve will tend to increase. Evidence of neutron production, as indicated by an actual increase of the area, will only be obtained if the gain through Q (neutron production) is greater than the loss through τ (neutron capture). This loss can anyway be studied separately, since it has been shown⁵ that the introduction of nuclei which act merely by capture or by increasing the hydrogen

content of the solution can affect the shape of the density curve only in a characteristic way: the modified curve can always be brought to coincide with the primitive curve by multiplying all abscissae by a suitable factor and all ordinates by another factor.

The accompanying graph shows the two curves obtained. At small distances from the source the neutron density is greater in the ammonium solution than in the uranyl solution; at distances greater than 13 cm., the reverse is true. In other words, the decrease of the neutron density with the distance is appreciably slower in the uranyl solution.

The observed difference must be ascribed to the presence of uranium. Since the two curves cannot be brought to coincide by the transformation mentioned above, the uranium nuclei do not act by capture only; an elastic diffusion by uranium nuclei would have an opposite effect: it would 'contract' the abscissae, instead of stretching them. The density excess, shown by the uranyl curve beyond 13 cm., must therefore be considered as a proof of neutron production due to an interaction between the primary neutrons and the uranium nuclei. A reaction of the well-known ($n, 2n$) type is excluded because our primary neutrons are too slow for such a reaction (90 per cent of Ra + Be photo-neutrons have energies smaller than 0.5 Mev. and the remaining 10 per cent are slower than 1 Mev.).

The degree of precision of the experiment does not permit us to attribute any significance to the small increase of the area in the uranyl curve (as compared to the ammonium curve), which we obtain by extrapolating the curves towards greater distances. In any event, an inferior limit for the cross-section for the production of a neutron can be obtained by

assuming that the density excess due to this production is equal throughout the whole curve to the excess observed at $r = 25$ cm.; this limit, certainly inferior to the actual value, is 6×10^{-22} cm.³.

Our measurements yield no information on the energy of the neutrons produced. If, among these neutrons, some possess an energy superior to 2 Mev., one might hope to detect them by a (n, p) process, for example, by the $^{32}\text{S}(n, p)^{32}\text{P}$ reaction. An experiment of this kind, Ra γ - Be still being used as the primary neutron source, is under way.

The interest of the phenomenon observed as a step towards the production of exo-energetic transmutation chains is evident. However, in order to establish such a chain, more than one neutron must be produced for each neutron absorbed. This seems to be the case, since the cross-section for the liberation of a neutron seems to be greater than the cross-section for the production of an explosion. Experiments with solutions of varying concentration will give information on this question.

Products of the Fission of the Uranium Nucleus

O. Hahn and F. Strassmann¹ have discovered a new type of nuclear reaction, the splitting into two smaller nuclei of the nuclei of uranium and thorium under neutron bombardment. Thus they demonstrated the production of nuclei of barium, lanthanum, strontium, yttrium, and, more recently, of xenon and caesium.

It can be shown by simple considerations that this type of nuclear reaction may be described in an essentially classical way like the fission of a liquid drop, and that the fission products must fly apart with kinetic energies of the order of hundred million electron-volts each². Evidence for these high energies was first given by O. R. Frisch³ and almost simultaneously by a number of other investigators⁴.

The possibility of making use of these high energies in order to collect the fission products in the same way as one collects the active deposit from alpha-recoil has been pointed out by L. Meitner (see ref. 3). In the meantime, F. Joliot has independently made experiments of this type⁵. We have now carried out some experiments, using the recently completed high-tension equipment of the Institute of Theoretical Physics, Copenhagen.

A thin layer of uranium hydroxide, placed at a distance of 1 mm. from a collecting surface, was exposed to neutron bombardment. The neutrons were produced by bombarding lithium or beryllium targets with deuterons of energies up to 800 kilovolts. In the first experiments, a piece of paper was used as a collecting surface (after making sure that the paper did not get active by itself under neutron bombardment). About two minutes after interrupting the irradiation, the paper was placed near a

Geiger-Müller counter with aluminium walls of 0.1 mm. thickness. We found a well-measurable activity which decayed first quickly (about two minutes half-value period) and then more slowly. No attempt was made to analyse the slow decay in view of the large number of periods to be expected.

The considerable intensity, however, of the collected activity encouraged us to try to get further information by chemical separations. The simplest experiment was to apply the chemical methods which have been developed in order to separate the 'transuranium' elements from uranium and elements immediately below it⁶. The methods had to be slightly modified on account of the absence of uranium in our samples and in view of the light element activities discovered by Hahn and Strassmann¹.

In these experiments, the collecting surface was water, contained in a shallow trough of paraffin wax. After irradiation (of about one hour) a small sample of the water was evaporated on a piece of aluminium foil; its activity was found to decay to zero. It was checked in other ways, too, that the water was not contaminated by uranium. To the rest of the water we added 150 mgm. barium chloride, 15 mgm. lanthanum nitrate, 15 mgm. platinum chloride and enough hydrochloric acid to get an acid concentration of 7 per cent. Then the platinum was precipitated with hydrogen sulphide, in the usual way; the precipitate was carefully rinsed and dried and then placed near our counter.

The results of three such experiments were found to be in mutual agreement. The decay of the activity was in one case followed for 28 hours. For comparison, a sample of uranium irradiated for one hour was treated chemically in the same way. The two decay curves were in perfect agreement with one another and with an old curve obtained by Hahn, Meitner and Strassmann under the same conditions. In the accompanying diagram the circles represent our recoil experiment while the full line represents the uranium precipitate. A comparison of the activity (within the first hour after irradiation) of the precipitate and of the evaporated sample showed that the precipitate contained about two thirds of the total activity collected in the water. After about two hours, however, the evaporated sample was found to decay considerably more slowly than the precipitate, presumably on account of the more long-lived fission products found by Hahn and Strassmann¹.

From these results, it can be concluded that the 'transuranium' nuclei originate by fission of the uranium nucleus. Mere capture of a neutron would give so little kinetic energy to the nucleus that only a vanishing fraction of these nuclei could reach the water surface. So it appears that the 'transuranium'

periods, too, will have to be ascribed to elements considerably lighter than uranium.

In conclusion, we wish to thank Dr. T. Bjerge, Dr. J. Koch and K. J. Broström for putting the high-tension plant at our disposal and for kind help with the irradiations. We are also grateful to Prof. N. Bohr for the hospitality extended to us at the Institute of Theoretical Physics, Copenhagen.

Radioactive Organic Bromo-Compounds

CONSIDERABLE attention has recently been focused on the use of artificially radioactive substances in biological work. The radioactive isotope ⁸²Br has been chosen by us because it has a conveniently long half-life (34 hours), it is chemically reactive, it gives off gamma-rays which aid in its detection, and finally, it can be prepared from ⁸¹Br either by the action of slow neutrons or deuterons. Slow neutrons are easily available from the radon-beryllium reaction. Fast deuterons from the cyclotron or any other suitable high-energy source may be used either as projectiles themselves or for the production of slow neutrons as in the lithium reaction below. The relative abundance of ⁸¹Br in natural bromine is 49.3 per cent. Contamination of radioactive ⁸²Br by other isotopes is of no consequence since bromine forms no non-bromine radioactive elements on bombardment by slow neutrons or deuterons¹.

Two reactions have been studied. The first is the Sandmeyer reaction for the introduction of bromine into the benzene ring. 345 c.c. of water containing 50 gm. Cu₂Br₂, 175 gm. NaBr.2H₂O and 30 c.c. HBr (density 1.49) was bombarded by slow neutrons produced from lithium with 900 kev. deuterons. 250 gm. of CHBr₃ was also bombarded. The glass vessels were surrounded by thick blocks of paraffin. Two experiments were then performed. 115 c.c. of the solution called the Sandmeyer solution was shaken with the whole of the bombarded CHBr₃ to concentrate the radioactivity², then separated off and extracted with CHCl₃. 14.5 gm. of C₆H₅NH₂ was diazotized in the usual manner and 11.8 gm. of C₆H₅Br prepared, called C₆H₅Br (1). Another sample, called C₆H₅Br (2), was made from a second 115 c.c. of the Sandmeyer solution, not shaken with the CHBr₃. As expected, attempts to exchange the radioactive bromine in C₆H₅Br by shaking with NaBr were wholly unsuccessful.

Table 1 shows the radioactivity per gram atom of bromine compared to that of the Sandmeyer solution before concentration of the radioactivity. Measurements were made with a thin-walled Geiger-Muller

counter. The samples were in glass vessels and the measurements were made nearly simultaneously to obviate corrections due to radioactive decay. It is to be emphasized that, although care was taken to keep the geometry constant, the results can only be taken as qualitative.

TABLE 1

	Relative radioactivity per gram atom Br.
Sandmeyer solution	1.0
CHBr ₃ before enrichment of Sandmeyer solution	2.5
CHBr ₃ after enrichment	1.4
C ₆ H ₅ Br (1)	4.2
C ₆ H ₅ Br (2)	0.5
C ₆ H ₅ Br (1) after shaking with NaBr	4.2

The second technique is the addition of bromine to a double bond. 100 gm. CH₃Br₂ was irradiated with slow neutrons and after irradiation 0.2 c.c. of bromine was added. Three hours later 1.2 gm. of cholesterol in 12 c.c. of ether was added, and the CH₃Br₂ distilled off in vacuum. The crystalline residue was dissolved in ether and recrystallized. Table 2 shows the relative radioactivity per gram atom of bromine compared with the irradiated CH₃Br₂. Experiments with CHBr₃ in place of the CH₃Br₂ yielded an oil from which the cholesterol dibromide could not be separated.

TABLE 2

	Relative radioactivity per gram atom Br.
CH ₃ Br ₂ before enrichment	1.0
CH ₃ Br ₂ after enrichment	0.5
Cholesterol dibromide	300

The first method does not yield such a high concentration of radioactive material. It may be of use in the labelling of halogenated molecules and the determination of their fate in the body. The second technique gives a very high concentration of radioactivity. It is hoped to obtain concentrations high enough to enable us to study the effect of artificial radioactivity on normal and pathological tissues. Further work will be done along these lines.

We wish to express our thanks to the members of the Cavendish High Tension Laboratories for help in the slow neutron bombardments.

Catalytic Exchange of Deuterium and Hydrogen in Hydrocarbons

IN a recent communication¹, L. and A. Farkas have followed the exchange of deuterium for hydrogen in cyclohexane and hexane on platinized foil at relatively low temperatures. They suggest that the catalytic mechanism for both saturated and unsaturated hydrocarbons involves the primary detachment of a hydrogen atom from the hydrocarbon. We have had occasion to examine the mechanism of catalytic exchange with olefines by a number of different methods, and have come to the definite conclusion that the primary act in the case of olefines is the addition and not the loss of a hydrogen atom.

This conclusion is supported by experiments on the effect of hydrogen both on double bond migration and on ring closure in olefines.

Further, in the case of saturated hydrocarbons, catalytic exchange, degradation and dehydrogenation all appear to involve hydrogen in the chemisorption process, but the experimental data are not as yet so conclusive as is the case for the olefines. If further experiments support this point of view, it might be suggested that the simplest representation of the hydrocarbon catalyst hydrogen system is as follows:

where (i) chemisorbed hydrogen reacts with a Van der Waals adsorbed saturated hydrocarbon group, or (iii) a chemisorbed olefine reacts with a Van der Waals adsorbed molecule of hydrogen each producing the common transition complex, (ii).

This simple formulation offers a ready interpretation of the various reactions observed in these systems. It is hoped that opportunity will present itself in the forthcoming meeting of the Faraday Society for an adequate discussion on the elementary steps operative in hydrocarbon catalytic reactions, reactions of far-reaching importance, and on the nature of which there is clearly as yet no unanimity.

Chemical Aspects of the Cyclol Hypothesis

CONSIDERABLE discussion of the structure of proteins, especially in relation to the cyclol hypothesis, has recently appeared in NATURE^{1,2,3}. This theory assumes that globular proteins consist of a space-enclosing arrangement of diazine and triazine rings. Most of the evidence produced (including the X-ray diagrams^{4,5}) is, however, not specific for the cyclol theory; many of the points made by Langmuir⁴ could be equally well used as an argument in favour of any regular geometrical structure which joins peptide chains to form a globular molecule. It is indeed possible to suggest bonds between peptide chains of types already known to exist; thus we are familiar with compounds containing the linkages S—S, CO—S, NH—S or CO—NH—CO, all of which might occur in proteins; in addition, the possibility exists of linkages between hydroxyl groups of hydroxy-amino acids and free carboxyl groups.

The more specific points of evidence in support of the cyclol theory are: (a) it claims to predict molecular weights of the order of magnitude found with the ultracentrifuge; (b) it conforms with the regularities in the amino acid composition of proteins (Bergmann and Niemann); (c) it gives a reasonable picture of denaturation as 'deacyclization' or change from cyclol to chain structure.

(a) Wrinch assumes that egg albumin contains 288 residues; on the other hand, Svedberg⁶ finds a

molecular weight of 40,500 or 43,800, which would lead to average residue weights of 159 and 170 respectively. Since it is known that egg albumin does not consist mainly of 'heavy' amino acids, such as tyrosine, tryptophane or arginine, the value of 288 cannot be accepted for the number of residues in egg-albumin.

(b) The regularities in amino acid composition deduced by Bergmann and Niemann are based on analytical results which are not sufficiently accurate to be statistically significant⁷.

(c) If denaturation consists of deacyclization, it should occur in all globular proteins having a cyclol structure and not in fibrous proteins. Actually, insulin, a globular protein which has been extensively studied in connexion with the cyclol theory, cannot be denatured in the usual sense of the word; it is very resistant towards heat or acid, and it can even be recovered in crystalline form after esterification with acid alcohol followed by treatment with dilute alkali⁸. On the other hand, a fibrous protein, like myosin, for which no cyclol structure can be claimed, denatures easily at temperatures above 40°.

Further, it seems difficult to reconcile the reversibility of denaturation^{9,10} found for serum albumin with the supposed instability of cyclol rings. Another difficulty is that low-molecular peptides or diketopiperazines would be expected to be found when the cyclol structure breaks down. Actually, no such low-molecular compounds are liberated on denaturation. It follows, therefore, that the cyclol theory cannot satisfactorily explain the facts of denaturation.

To explain the behaviour of proteins towards enzymes, Langmuir and Wrinch¹ assume that denaturation occurs before the enzyme can attack the protein molecule. This may be the case for many proteins; but insulin is hydrolysed by pepsin or trypsin under conditions in which the insulin molecule is perfectly stable. Here enzymic hydrolysis must take place without previous denaturation. In order to explain these facts, the unwarranted assumption would have to be made that the enzyme not only hydrolyses the protein, but also deacyclizes it.

Attempts to prove the cyclol structure in proteins have failed so far (see, for example, Haurowitz¹¹), nor has it been possible to synthesize simple models of the cyclol type in the laboratory; the physical evidence for the hypothesis is most uncertain¹², and the lactam-lactim tautomerism of peptides, which is the chemical basis of the cyclol theory, has never been demonstrated by either physical or chemical methods. Is it surprising, therefore, that chemists are reluctant to accept a structure for which no analogue in organic chemistry can be found?

Chromatographic Fractionation of Whale-Liver Oil

Pritchard, Wilkinson, Edisbury and Morton¹ have already reported striking disagreement between the biological activity and the absorption at 328 m μ of the concentrates of mammalian liver. As we had formerly used the Carr-Price reaction to a great extent for practical determinations, we were interested in its relation to ultra-violet absorption and to biological activity. We therefore fractionated whale-liver oil and determined the blue colour with trichloride of antimony, the curve for the ultra-violet absorption, and the biological activity, of the various fractions thus obtained.

The fractionation was carried out in the following way: The oil was first saponified, after which the part that could not be saponified was given further treatment. (We offer our best thanks to Messrs. Ferrosan and Co., Ltd., Copenhagen, for so kindly supplying a large quantity of the unsaponifiable part of whale-liver oil.) The sterols were eliminated by crystallization from methyl alcohol, first in an ice-box, and then by freezing in solid carbon dioxide and acetone. The soluble part was dissolved in petroleum-ether and submitted to chromatographic separation with calcium hydroxide as an adsorbent. Painting with antimony trichloride, as described by Zechmeister, Chohnoky and Ujhelyi², gave a positive reaction for the whole length of the column, and the adsorption column was, therefore, divided arbitrarily into four parts, from which vitamin A was eluted by petroleum-ether containing a little methyl alcohol. The top fraction gave a red-violet reaction towards antimony trichloride, which, according to our standard curve, would have meant about 101,000 I.U. per gm. activity of vitamin A. Biological assay, however, showed that it was quite inert. The next fraction should have contained 3,160,000 I.U. per gm., according to the antimony trichloride reaction, but the biological activity was 1,160,000 I.U. per gm. It has been impossible, unfortunately, up to the present to evaluate the ultra-violet absorption on account of lack of material. All three determinations are, however, available for the third and fourth fractions:

	III	IV
Biological activity ..	531,000 I.U./gm.	531,000 I.U./gm.
Antimony trichloride value ..	950,000 "	1,160,000 "
Ultra-violet absorption at 328 m μ ..	384,000	382,000 "

The biological activity is thus considerably lower than would have been expected from the antimony trichloride reaction. The biological activity is greater than might have been expected from the ultra-violet absorption, but not so much, when the number of animals used for the biological assay is taken into consideration. The absorption maxima for the ultra-violet curve are not, however, at 328 m μ , but are displaced towards the short-wave part—more exactly, at 293 m μ .

The investigations of Gillam, Heilbron, Jones and Lederer³ showed that there is a substance in the liver of freshwater fish with vitamin A activity, the absorption maximum of which is at 344 m μ . This substance does not occur alone, but together with the ordinary vitamin A. It has, however, not been possible to produce the actual substance in pure form, though the English investigators were able to determine the chemical constitution of the new substance by preparing suitable derivatives.

According to our experiments, whale-liver oil does

not contain this substance. The ultra-violet absorption at wave-lengths longer than 328 m μ is weak even for our chromatographic fractions, and we cannot find a maximum for the antimony trichloride reaction at 690 m μ . On the other hand, the maxima for the ultra-violet absorption of our fractions III and IV agree well with the results given by Pritchard, *et al.*

It has already been shown many times that the maximum absorption occurs at 570–580 m μ for the antimony trichloride reaction of vitamin A. Chromogen 610 and chromogen 570 were separated by adsorption on to fuller's earth⁴ in Wolff's laboratory. Karrer, Morf and Schöpp⁵ isolated the so-called hepaxanthin, the absorption maximum of which is at 270 m μ . Hepaxanthin is not thought to have any biological activity.

Since our highly purified products, however, show greater absorption for the antimony trichloride reaction at 570 m μ than at 610 m μ , have a distinct maximum in the ultra-violet field at about 290 m μ , and possess biological activity which, as has been mentioned, is considerably greater than that corresponding to the absorption at 328 m μ , it does not seem to be impossible that our preparations contain a hitherto unknown substance with the biological action of vitamin A.

Formation of Negative Ions by Negative-Ion Bombardment of Surfaces: a New Process

EXPERIMENTS with a double mass-spectrograph have been described recently by one of us and R. Press¹. These show conclusively that bombardment of a gas-contaminated surface with positive ions of one species can produce a spectrum of negative ions. In this work particular attention was directed to the process involved. We have now extended these experiments, in the first place, to identify some light ions, the identity of which was not definitely established in the earlier work. By calibrating the mass-spectrograph with a Kussman alkali ion source, used in such a way that the magnet current did not have to be altered from the value used during the negative ion runs, we have identified accurately the main negative ion peaks, with results in general accord with the early work of Woodcock² (which we had previously overlooked), and with that of Arnot and Beckett³.

We have also studied the emission of negative ions from oxide-coated cathodes, which can be liberated either by heating⁴ or by positive ion bombardment⁵. During an investigation of the energy distributions of these ions, an interesting effect was observed. A wire gauze had been inserted between the cathode

and the first slit of the mass-spectrograph to permit of the electric field at the cathode being held constant, while the energy of the ions entering the first slit was varied. A diffuse negative ion peak in the region of mass numbers 24-26 was found to be multiple, with some of the ions showing energies in excess of those imparted to them by the accelerating electric fields. When the potential difference between the gauze and cathode was increased, the two main components separated, but one remained in the original position in the mass spectrum ($M = 26$). This shows that it was due to ions from the cathode, while the other was due to ions from the gauze. If the latter had been produced by positive ion bombardment of the gauze, then one would expect the cathode and its supports to have been similarly bombarded and negative ions to have been liberated from them with large initial energies. However, investigation of the energy distribution of the ions liberated from the cathode revealed that no ions were present with mutual energies, so indicating the absence of any appreciable positive ion bombardment of this electrode, since such bombardment is known to liberate ions with initial energies¹. In the absence of positive ion bombardment, we are forced to the conclusion that the negative ions from the gauze are emitted as a result of bombardment of the latter by negative ions from the cathode. The ions so emitted, like those produced by positive ion bombardment, show excess energies.

The peak from the gauze in the region $M = 26$ is complex, and is found when examined under sufficient resolution to consist of three peaks due to ions of masses 24, 25 and 26, possibly C_2^- , C_2H^- and CN^- . Cl_{35}^- and Cl_{37}^- have also been detected from the cathode, but not from the gauze under the same conditions.

This new process seems to account for an effect observed by Bachman and Carnahan², who have published photographs of the negative ion spectrum which they were able to produce on the screen of a cathode ray oscillograph. In one case, when an oxide-coated cathode was broken down after the tube was sealed off from the pumps, they recorded a circle surrounding the spot due to the ion of mass 26. Since this tube was slightly soft, due to liberation of gas during the activation of the cathode, it is possible that the ring was produced by positive ion bombardment of one of the apertures in the vicinity of the cathode. However, in the case of a hard tube containing a hairpin tungsten filament, they obtained several circles in the spectrum. It is almost certain that these are due in part to bombardment of an aperture by negative ions from the filament. Unfortunately, Bachman and Carnahan do not give details of their focusing fields, so that a quantitative check is not possible.

A similar negative ion emission is to be expected from some of the grids of commercial multi-electrode thermionic valves with oxide-coated cathodes.

Oxidation of Reduced Codehydrogenase I

THE discovery of an enzyme^{1,2} capable of catalysing the oxidation of reduced codehydrogenase I (cozymase, CoI) at an extremely rapid rate³ naturally raises the question as to what part this enzyme plays in hydrogen transport. There is considerable evidence^{1,2,4,5} that this enzyme (diaphorase) catalyzes the reaction between dihydrocozymase and the cytochrome system, and Dewan and Green⁶ have suggested that cytochromes *A* and *B* (but not *C*) and cytochrome oxidase are involved. The method of preparing diaphorase is such that succinic acid dehydrogenase is also present in large amounts. With the possible exception of the recent announcement⁷ that diaphorase had been obtained in highly purified form, it seems fairly certain that most of the data in the literature regarding either enzyme were obtained with preparations containing both enzymes. This statement has a very important bearing on the 4-carbon acid catalysis theory of Szent-Györgyi, since it raises the question as to the possibility that succinic acid dehydrogenase is an intermediary hydrogen carrier between diaphorase and cytochrome.

The present work was begun with the purpose of finding the path by which hydrogen proceeds from dihydrocozymase over diaphorase to molecular genoxy. The succinic acid dehydrogenase preparation of Stotz and Hastings⁸ was used as a source of diaphorase. This preparation is an alkaline phosphate extract of washed pig heart muscle, with fumarase inactivated (enzyme *A*). This enzyme is in the form of a dispersion which does not settle out. It was shown to contain diaphorase, succindehydrogenase, cytochrome, and cytochrome oxidase, and small amounts of triose phosphate dehydrogenase. In addition, a dialysed extract of acetone powder from rabbit skeletal muscle⁹ (enzyme *B*) was used as a source of triose phosphate dehydrogenase and xymohexase. Considerable work was done with dry preparations but in these there was no reaction between CoH_2I and oxygen until dye was added.

The reactions involved in this work may be written as follows:

By using an excess of enzyme *B*, cozymase, and hexose diphosphate in the presence of fluoride, and determining the amount of enzyme *A* which limited oxygen uptake, it was possible to study reaction (4) using amounts of enzyme *A* which gave approximately half maximum rates of oxygen uptake. Parallel experiments were always run with an equal amount of enzyme *A* using succinic acid as substrate. This demonstrated the presence of succindehydrogenase and the cytochrome system.

It was found that fresh preparations of enzyme¹⁰ *A* were capable of bringing about reactions (4) and (5) at an extremely rapid rate; but that after about five days at 4° C. the activity was nearly completely destroyed. Crucial experiments were therefore performed at various times after the enzyme was prepared. Since neither the diaphorase nor the succindehydrogenase were appreciably destroyed in this period, it appears that the destruction occurs in the cytochrome oxidase or possibly in cytochrome *B*.

This point is being studied further. The fact that the rate of reaction (4) appears to decrease faster than the rate of reaction (5) suggests that different cytochromes may be involved.

EFFECT OF STANDING ON THE ENZYME SYSTEMS WHICH OXIDISE CoH_2I AND SUCCINIC ACID. 0.2 C.C. OF ENZYME A IN ALL CASES. HEXOSE DIPHOSPHATE SUBSTRATE FOR CoH_2I OXIDATION.

Expt. No.	Hours since preparation	CoH_2I oxidation		Succinate oxidation 0-30 min.
		0-30 min. no dye	30-60 min. + brilliant cresyl blue	
14 IA	24	cub. mm. O_2 205	cub. mm. O_2 63	cub. mm. O_2 182
14 IIA	30	197	65	176
14 IIB	48	195	—	168
14 IIC	90	40	72	70 (+ cytochrome, IIS)

The accompanying table also shows the effect of adding brilliant cresyl blue to the CoH_2I oxidation. It appears that the ability of the dye to inhibit or activate the CoH_2I oxidation depends on the state of activity of the natural carriers in the preparation. A similar observation has been made in the case of the succinoxidase system⁶, in which brilliant cresyl blue was found to be the dye which transported hydrogen most rapidly in the inactive system and inhibited an active system the least. Although cytochrome C increased the oxygen uptake in the case of succinate plus the ninety-hour preparation, it had virtually no effect on the CoH_2I oxidation at ninety-six hours. This is in agreement with the findings of Dewan and Green⁵.

With reference to the possibility of reaction (5) as an intermediate step in reaction (4), it is highly significant that $M/150$ malonate had absolutely no effect on CoH_2I oxidation as observed in the conditions in the table, while it produced 100 per cent inhibition in the case of succinate oxidation using the same enzyme preparation. Furthermore, it was found that fluoride strongly inhibited succinate oxidation in these experiments but had no effect on the initial rate in the case of CoH_2I oxidation. Fluoride does not inhibit CoH_2I oxidation; the rate of oxygen uptake actually becomes somewhat greater in this system when CoH_2I is oxidized in the presence of fluoride. This is quite likely due to the fact that in the absence of fluoride, reaction (3) can proceed yielding pyruvic acid which can compete for the dihydrocozymase hydrogen. This explanation is further borne out by the fact that addition of magnesium ions, which are known to activate reaction (3), in the absence of fluoride, gives a further decrease in the rate of CoH_2I oxygen uptake.

Additions of fumarate had no effect on the CoH_2I oxidation in the conditions shown in the table, in the presence or absence of fluoride. These negative results can be explained by the probability that cytochrome was the limiting reactant in the fresh enzyme; but it must be observed that in the ninety-hour preparation there was enough succindehydrogenase and its carrier system to give an oxygen uptake of 70 cub. mm. in comparison with the 40 cub. mm. observed for the CoH_2I oxidation. It is of course true that as the oxidase system becomes weaker, the competing effect of the α -glycerophosphate dehydrogenase in enzyme B probably becomes more pronounced.

These observations do not suggest that the 4-carbon catalysis theory of Szent-Györgyi is wrong. They merely

point out that the enzyme diaphorase is a widely distributed, powerful, malonate-insensitive enzyme which catalyzes the transport of CoH_2I hydrogen to natural carriers which are capable of bringing this hydrogen ultimately to oxygen. The known facts of fumarate catalysis and malonate inhibition in muscle respiration must somehow be reconciled with this observation. The fact that factors tending towards pyruvate formation lessen the oxygen uptake of the system studied here may be a clue as to the mechanism of fumarate catalysis and malonate inhibition. It is possible that fumarate catalysis is to be explained in terms of pyruvate removal. It should also be pointed out that the observation that rapid CoH_2I oxidation can proceed without the action of succindehydrogenase does not prove that the oxidation of CoH_2I does not involve succindehydrogenase in the intact system. Further work is being done in an attempt to establish the nature of the fumarate catalysis in the light of these results.

I am indebted to Prof. Hans v. Euler and to Dr. Erich Adler for laboratory facilities and helpful criticism during this work.

Time-to-Time Variation in the Response of Ovariectomized Mice to Oestrone

IN *NATURE* of October 8, 1938, Duszyńska gave an account of seasonal variation in the response of ovariectomized mice to oestrone, and described an annual cycle of sensitivity which was greatest in spring and lowest in autumn. In the accompanying figure, I have plotted the variations in the dose of international standard oestrone needed to give 50 per cent positive responses when given by injection to groups of ovariectomized mice belonging to colonies kept at this Institute during the past twenty months.

A standard assay technique has been adhered to throughout the whole of this period, most of the determinations having been made with two or three groups of twenty mice each; but some with only a single group of twenty mice (notably those in which determinations for the first colony, denoted by black dots, overlap those for the second colony, denoted by open circles). Whilst an undoubted time-to-time variation in sensitivity occurs, it does not in this instance seem to follow any regular trend. It has been shown that mice which receive sufficient oestrogen to elicit a positive response within six weeks before use are fully 'primed'. The mice in question were therefore uniform in that all groups had received oestrogenic material in sufficient amount within the necessary period before their use as controls.

The colonies have been kept at a fairly uniform temperature, but were exposed to the normal changes in daylight. Attempts to discover the causes of sensitivity changes have shown, however, that mice

kept in an ice-chest and in continuous darkness give the same response as the normal controls, while those continuously illuminated throughout the test period

Terminology in Biology

DR. C. D. DARLINGTON¹ raises a very important point in his condemnation of words which should be dead but are still in biological currency. Every teacher and every author of a text-book will sympathize. The beginner in biology has a hard enough task without having to be plagued by a spate of alternative terms, an infliction which too often leads him to think that all he has to do is to learn these terms and their synonyms in order to 'know' his subject. To many students, a thing is known and understood as soon as a label has been attached to it. There is little wonder that biology is so subject to the reproach that it is nothing but a jumble of difficult words.

Unfortunately we are in a vicious circle. The teacher feels bound to give the alternative terms in case the student comes across them in his reading, and the author of a text-book considers it his duty to give the synonyms because teachers vary in their usage. Unless something is done, we shall have with us for evermore 'anterior vena cava', 'superior vena cava' and 'precaval vein'; and 'antherozoid' and

'spermatozoid'; and the host of alternative names for the female gametes of plants.

Cannot biologists get together and draft a list, with clear definitions, of the technical terms in common usage in botany and zoology? The selection should not be based on priority of introduction, but on commonsense suitability and expressiveness (for example, 'neural tube' is surely more understandable to the student than is 'medullary tube', and 'antheridium' is certainly preferable to 'pollinodium'). Possibly the British Association could take up this matter, or maybe the Association of British Zoologists would be willing to co-operate with a group of botanists in an attempt to clean up the present confusion.

Points from Foregoing Letters

THE possibility of an evaporation of neutrons in connexion with the recently discovered explosion of the uranium nucleus after neutron impact is discussed by Dr. H. von Halban, jun., Prof. F. Joliot and Dr. L. Kowarski. The density distribution of thermal neutrons obtained by slowing down photo-neutrons from a Ra γ - Be source was studied in a solution of uranyl nitrate and in an equivalent solution of ammonium nitrate. At great distances from the source the uranyl solution showed an excess interpreted as a proof of the existence of the effect discussed.

Prof. L. Meitner and Dr. O. R. Frisch have collected recoil nuclei resulting from the fission of uranium nuclei, by placing a water surface near the bombarded uranium layer. From chemical tests and decay curves, the authors conclude that a considerable part of the collected activity corresponds to the 'trans-uranium' elements previously studied by Hahn, Meitner and Strassmann. Consequently the 'trans-uranium' decay periods must result from a fission of the uranium nucleus and therefore have to be assigned to elements considerably lighter than uranium.

Experiments are described by Prof. E. Friedmann, A. K. Solomon and N. T. Wertheessen which give the relative amounts of radioactive bromine ⁸²Br introduced into organic compounds by means of two processes—Sandmeyer's reaction and the addition of bromine to a double bond. The second method yields a higher concentration of radioactivity.

S. R. Craxford, G. H. Twigg and Prof. Eric K. Rideal point out that, contrary to the views of L. and A. Farkas in the catalytic exchange reaction between deuterium and olefines, the elementary step involves the addition of a deuterium atom and not a loss of a hydrogen atom. There is also evidence that in the chemisorption and rupture of saturated hydrocarbons on a catalyst surface, chemisorbed hydrogen plays a part. If this receives confirmation, a simple mechanism can be proposed permitting an inter-

pretation of the great variety of chemical reactions which hydrocarbons can undergo at catalyst surfaces.

Dr. A. Neuburger contends that the evidence for the cyclol hypothesis, derived from the phenomena of denaturation, of molecular weights and regularities in the amino acid composition of proteins, can be otherwise interpreted. He claims that one may arrive at a globular structure for the protein molecule by postulating, instead of cyclol bonds, other types of bonds which are already known to exist. A reply to Neuburger's suggestions is given by Dr. Dorothy Wrinch on p. 482.

The biological activity of various fractions of a whale-liver oil concentrate (fractionated by adsorption in a calcium hydroxide column) is found by H. Willstaedt and Dr. H. B. Jensen to be considerably lower than would have been expected from the antimony trichloride reaction, but greater than shown by the ultra-violet absorption. Apparently the whale-liver oil does not contain the active substance with an absorption maximum at 344 m μ but may contain another hitherto unknown substance having the biological action of vitamin A.

The liberation of negative ions from a wire gauze inserted between the cathode and the first slit of a mass-spectrograph is reported by R. H. Sloane and Miss Eliza B. Cathcart. The ions so emitted under negative ion bombardment, like those produced by positive ion bombardment, show excess energies.

The role of the enzyme diaphorase as a hydrogen carrier is discussed by V. R. Potter, who concludes that diaphorase is a widely distributed, powerful, malonate-insensitive enzyme which catalyses the transport of hydrogen from dihydrooxymase I to natural carriers capable of bringing this hydrogen ultimately into combination with oxygen.

C. W. Emmans reports that, while his colonies of ovariectomized mice exhibit time-to-time variation in sensitivity to injected oestrone, the variations do not show any regular trend.

Research Items

Early Settlers in Virginia

In the course of the recent meeting of the American Association for the Advancement of Science, at Richmond, Va., during December 27-31, R. Bennett Dean presented a study of early settlements of various nationals in the Colony. Of the French the first to land came with the Governor, Lord De la Warr, in 1610. They planted vines and mulberry groves and were responsible for the establishment of the silk industry. In succeeding years of the seventeenth century, great numbers of Huguenots followed, especially from Saintonge, Languedoc and the Gironde; but the greatest single movement took place about 1700, when on one occasion four boats with about eight hundred passengers sailed from London. After the revocation of the edict of Nantes in 1685 more than 1,000 settled at Mannakin on the upper James. By 1800 the French had spread to nearly every community in Virginia. The highest percentage is now in Powhattan county. Four Germans were in the first boat to arrive at Jamestown. By 1623 there were at least 109 German, Swiss and Dutch, chiefly, artisan, settlers in Virginia. Two thousand immigrants from the Rhenish Palatinate in 1707 were the ancestors of the settlers in the Valley of Virginia. Between 1690 and 1716, the persecution of the Protestants in Germany brought settlers to the forks of the Potomac. Some afterwards moved into the Shenandoah valley. These now are the areas with the highest percentage of Germans. One of the earliest settlements of the Scots was in 1649, when 320 Royalists arrived. In 1732 Scots, largely from Pennsylvania, entered the Valley, founding Presbyterianism in the United States. More numerous and more active than the Germans, they spread over and outside the State, and were an effective buffer against the Indians along the Alleghenies, enabling the colonists to consolidate their gains. In the earlier period of its history, Richmond was entirely occupied by Scots.

Mbali of Southern Angola

The designation 'Mbali', according to the interpretation given by the people themselves, means 'civilized black'. These people may be defined, according to the Rev. P. E. C. Estermann (*Africa*, 12, 1; 1939), as descendants of former slaves, who through employment on plantations, have assimilated a large number of the cultural elements of their old masters, and at the present day readily take to earning their livelihood among the Whites as domestics and artisans. The language of this people, originally of a mixed origin, is Kimbundu, mingled plentifully with Bantuized Portuguese terms. Their material culture has almost completely given way to elements which have been imported from Europe; but in mentality and in beliefs they are still predominantly Bantu. This appears especially clearly in their behaviour in relation to sickness and death. Belief in the incidence of sickness as due to the action of sorcerers is general. The medicine man is as much diviner as healer. The Mbali resort to them no less readily than do other natives, though the ritual employed differs in details, more especially in

the introduction of certain Christian features. The healing ceremonial culminates in a sacrifice of a victim which is killed by the patient after the onset of 'possession'. As the victim falls, the patient throws himself upon it and drinks the warm blood. In burial ceremonial, before the body is committed to the grave, the widespread Bantu rite of interrogation of the dead is performed. Two men raise the shroud, while a third asks the deceased who has been responsible for his death, slaying him by sorcery. If the sorcerer is present, this will be indicated by the movement of the shroud. If the person indicated is a man of courage or position, the accusation may be ignored. If, however, it should be a person of inferior standing, it may be that to avoid the consequent unpleasantness he will have to leave the country. Mourning lasts a fortnight and is brought to a close by a feast held at night, in which dances are accompanied by obscene songs.

Double Monsters

PROF. TAKU KOMAI and his colleagues have issued a series of four papers (*Mem. Coll. Sci. Kyoto Imper. Univ.*, B, 19, 155-253; 1938) dealing with the various types of twins and double monsters which occur in fishes, reptiles, birds and mammals. The literature is reviewed, and several new instances are given. The problem of situs inversus viscerum is recounted in some detail for fish embryos, and Komai comes to the conclusion that this curious derangement is associated with a disturbance of the normal developmental process and is due to a general, rather than a local, cause. There would appear to be a physiological gradient passing from the left to the right side of a fish embryo; and the derangement of this gradient brings about the situs inversus viscerum. Craniopegus, a rare form of duplicity in snakes, is described for *Hemibungarus japonicus*. The numerous types of katadidymi in chicks and ducklings are surveyed and tabulated in detail. Five specimens of mammalian double monsters are recorded. The many illustrations add to the usefulness of these papers.

Hæmoglobin Production in Anæmia

P. F. Hahn and G. H. Whipple (*J. Exp. Med.*, 69, 315; 1939) find that a low protein intake causes limited hæmoglobin production in anæmic dogs. The dog on a limited protein intake was unable to produce the usual amount of globin and therefore of hæmoglobin even in the presence of a large amount of iron. The same result was obtained whether the iron was given by mouth or intravenously, the dog, made anæmic by withdrawal of blood, being unable to produce the expected new hæmoglobin related to the iron intake when the protein intake was kept at low levels. The dogs could be kept in perfect health and weight equilibrium during these long periods of limited diet intake and anæmia. Under the stress of protein limitation, the proteins of salmon muscle, banana and carrot were well utilized, and only 7-8 gm. of these food proteins were required to produce 1 gm. of new hæmoglobin. These experiments clearly showed that the iron content of liver was not wholly responsible for its potency in anæmia due to hæmorrhage.

Reptiles and Amphibians of the Sahara

WE think of the Sahara as a region in which vegetation and, along with it, animal population are reduced to a minimum, yet in his two missions of exploration (1929-32 and 1934-35) H. Lhote contrived to capture alive 35 specimens of snakes, 115 lizards and 78 amphibians. His journeys traversed the Sahara from north to south, but they also touched the Sudan, and that to some extent accounts for the numbers of his specimens. With F. Angel he now describes the collections as representing the following numbers of species and subspecies: one crocodile and one chelonian, 25 lizards, 17 snakes, 8 frogs and toads (*Bull. Com. d'Etud. Hist. Sci. Afrique Occ. Française*, 21, 345; 1938). Several of the species are described as new to science. Perhaps the most interesting part of an ecological region of great diversity is the area Tanazrouft and Ténéré, the most desert of all the Sahara, forming a belt from Atlantic to Red Sea, which is an impassable barrier to all small species. Here the fauna is reduced to small forms able to subsist upon the sparse and scattered tufts of vegetation. The oases also constitute regions of ecological interest, for these isles of man-planted vegetation, lost in a vast sea of sand, form the only areas which can preserve the amphibians still persisting in the Sahara.

Evolution and Relationships of Elasmobranchs

J. A. MOY-THOMAS has recently reviewed the considerable amount of modern work on early fossil fishes and put forward his views regarding the evolution and relationships of the elasmobranchs (*Biol. Rev.*, Jan. 1939). Elasmobranchii has been used as synonymous with Chondrichthyes and not in the sense that it is used by some authors, who include in it a number of other early groups which the author, with justification, considers to be not closely related. The group arose in the Upper Devonian, and *Cladocelache* represents an approximation to the ancestral form. They early differentiated into two lines separable, *inter alia*, by their tooth structure, the Selachii and the Brachyodonti; the former having been derived from the Cladocelachii and including the living elasmobranchs, sharks, skates, rays, etc. The origin of the latter is not so clear, and their living representatives are the Holocephali. Reasons are given for regarding the Acanthodii, Arthrodira and other placoderms as not closely related to the elasmobranchs. They are a diverse group, with a number of characters in common, and are at a lower grade of evolution than the elasmobranchs.

Effect of Eupolyploidy on Chloroplasts

EUPOLYPLIDY in plants induces certain hereditarily changes such as increase in amount of nucleolar substance, increase in size of nucleus, amount of cytoplasm, volume of cells, etc. The size of the plants themselves is also affected; but the relation between euploid chromosome alteration and size varies, since some euploid plants are larger whereas others are smaller. The effect of eupolyploidy on the size of the chloroplasts has recently been studied by D. Kostoff and A. Orlov, working on *Nicotiana* and *Solanum* (*Ann. Bot.*, New Series, 2, No. 8, 883; 1938). From the data obtained, it is clear that chloroplasts do not increase with an increase in the chromosome number. In fact, there is a tendency to smaller size than in the diploids or in the parental species. In only one case (*N. rustica* × *paniculata*) was the average diameter of the chloroplasts of the amphidiploid larger than the average diameter of

those of the parent species. Since tetraploids are usually deeper green in colour, the colour difference is probably due to a larger number of chloroplasts in the cell.

Seeding from Severed Shoots

A DISCOVERY of importance to the farmer and gardener is the fact that once the flowers are open some of the common weeds can ripen their seeds on the severed shoot just as well as on the growing plant. N. T. Gill has carried out investigations into this question (*Ann. App. Biol.*, 25), and an account of his results is also given in the *Gardener's Chronicle* (No. 2716, 105). The most dangerous weeds in this respect are ragwort and sow thistle, for seed from out shoots of these species showed as good viability as when allowed to ripen completely on the parent plant. Out shoots of groundsel, on the other hand, gave only 35 per cent germination compared with 90 per cent from ripened seed. Other weed seeds such as dandelion, cat's-ear, creeping thistle, curled dock and stinging nettle can only germinate if the seeds are fully developed, but the inconspicuous nature of the flowers in some of these plants makes it unwise to assume that it is safe to leave out portions on the ground. The stage of maturity may also exert an influence on the length of dormancy of the seed. In the case of shepherd's purse, mature seeds can germinate in the autumn or spring, but half-ripe seeds wait until the spring. Corn speedwell and chickweed showed the same behaviour. *Datura stramonium*, on the other hand, behaved quite differently, for ripe seeds either germinated at once or lost their viability after four weeks, whereas immature seeds retained their germinative capacity for a year or more.

Frost Damage to Fruit Trees

THE serious reductions in crop suffered by fruit growers in recent years have led the Ministry of Agriculture to institute an inquiry into the effect of meteorological factors on the distribution of frost damage. Preliminary results obtained by C. E. Cornford have recently appeared (*J. Pom. and Hort. Sci.*, 16, 291; 1939). A study of micro-climate in relation to topography has brought out several interesting facts which may be of importance in attempts to combat frost injury. On certain clear nights when a calm exists in valleys, the occurrence of a light and relatively warm 'hill-top wind' has been demonstrated. This is able to influence the force and direction of a local katabatic wind on a neighbouring slope, producing a calm belt or 'neutral zone' across the slope, or a movement of air along the contours, according as the wind blows directly or obliquely on the slope. Such a calm belt may be a suitable site for orchard heaters. It was shown that on most radiation nights the air temperature over undulating country varied with altitude, the highest places being the warmest. The temperature, however, measured at a height of 3 ft. above the ground, was equally affected by the nature of the vegetation. The lowest minimum temperatures occurred over grassland, whilst the air above bare soil and that in woods with a complete leaf canopy was relatively warm, often 6° F. above that over grassland. Only exposed grass was able to produce relatively cold air above it on a radiation night, grass under trees in a leafy apple orchard causing no reduction. It is suggested that risk of frost damage in an orchard in the blossoming period may be reduced by reducing the amount of long grass exposed to the sky.

Anomalous Dispersion of Rayleigh Waves

THIS is the subject of a second paper on "Anomalous Dispersion of Elastic Waves" by K. Sezawa and K. Kanai (*Bulletin Earthquake Research Institute, Tokyo Imperial University*, 14, Part 4, November 1938). The densities and elastic constants of the surface layer and the subjacent material are symbolized, and the velocity equation of dispersive Rayleigh waves is determined in terms of these. Six cases of μ'/μ ranging from 1 to 0.4 are then assumed and the consequences investigated. It is found that when the stratification approximates to Wiechert's condition ($\varphi'/\varphi = \mu'/\mu = \lambda'/\lambda$), the velocity of Rayleigh waves for an intermediate value of L/H is considerably higher than that of the usual Rayleigh waves. In this particular instance there is a second dispersion curve that passes through the point corresponding to the velocity of Stonely waves. As the stratification approaches the usual type, the dispersion curve tends to assume the normal dispersion type. When density increases with depth more rapidly than elasticity, as may often occur in the earth, the dispersion curve becomes quite anomalous, and beyond a certain critical condition there should exist a range of L/H within which no surface waves of permanent type can exist.

Deep-Focus Earthquakes in Central Asia

S. P. LUN has made a study of four of these shocks occurring between 1933 and 1935, using data obtained from seismograms (*Seis. Bull.*, Chiufeng, China, Seismic Station, 3, Nos. 2 and 3; 1935 [received 1938]). The shocks were chosen by their characteristics as enumerated by Scrase and chiefly by their lack of notable l and m phases. The method of investigation was first to find the epicentre by assuming the travel time (T) of the P wave to be connected with the epicentral distance (Δ) by the formula $T = A + B\Delta + C(\Delta/10)^2$ and fitting in the constants A , B and C by the method of least squares, afterwards applying the Geiger method to correct the approximately determined epicentre. The depth of focus was then determined by four methods: (1) from first principles, (2) by the Brunner chart, (3) by Scrase's method, (4) by the time interval between $PKKS$ and P' . The results for the four shocks obtained by the author were as follows: (1) Epicentre φ 35° 29', λ 70° 05', T , 1933 Jan. 9d. 2h. 1m. 38s.; depth of focus, 0.045 of earth's radius. (2) Epicentre φ 36.1°, λ 70.7°, T , 1935 Feb. 3d. 2h. 10m. 42s., depth of focus 0.023 of earth's radius. (3) Epicentre φ 36.4°, λ 70.8°, T , 1935 April 3d. 11h. 11m. 56s., depth of focus 0.031 of earth's radius. (4) Epicentre φ 38.1°, λ 70.9°, T , 1935 Oct. 11d. 4h. 20m. 31s., depth of focus 0.047 of earth's radius. The author notes that the epicentres are all near φ 36°, λ 70°, near the inflexion of the Hindu Kush, and proposes to investigate the method of origin further.

Crystal Structure of Ammonium Cadmium Chloride

In crystalline cadmium chloride CdCl_2 , there are octahedral CdCl_6 groups condensed into layers, each chlorine atom being adjacent to three cadmium atoms. Tetrahedral co-ordination is shown by cadmium with cyanide groups in $\text{K}_4\text{Cd}(\text{CN})_6$, and with sulphur, selenium and tellurium atoms in the sphalerite and wurtzite type crystals CdS , CdSe and CdTe , and might occur with chlorine also. There are hence two types of structures which might well occur for the complexes $(\text{CdCl}_6)_n$, the first involving

octahedra with shared corners, as in the cubic crystal KMgF_3 , and the second involving rings or chains of tetrahedra as in the metasilicates. H. Brasseur and L. Pauling (*J. Amer. Chem. Soc.*, 60, 2886; 1938) have determined completely the structure of the orthorhombic crystal NH_4CdCl_4 , and find it to be based on octahedral configuration about the cadmium atoms. The CdCl_6 complexes occur in the crystal in infinite polymers in the form of double rutile strings of CdCl_6 octahedra parallel to the c -axis. These complexes are held together by the ammonium ions, each of which has nine chlorine atoms co-ordinated about it. Interatomic distances in the crystal are found to be closely related to those in CdCl_2 and NH_4Cl .

Large Cosmic Ray Showers

P. Auger, R. Maze, P. Ehrenfest and A. Fréon (*J. de Phys.*, 10, 39; 1939) have investigated very large showers of particles produced in the atmosphere by the cosmic rays. They find that Geiger counters separated by quite large distances (up to 75 m.) show occasional coincident discharges. The frequency of these extensive showers increases with altitude at much the same rate as the ordinary showers produced in heavy metals. It was concluded from the counter experiments that the density of particles in a shower was of the order of 50 per sq. metre, and a very similar result was obtained by the use of an expansion chamber released by the coincidences (cf. Jánosy and Lovell, *NATURE*, 142, 716; 1938). A great part of each shower consists of electrons, as shown by absorption and by the cascade multiplication of the particles in a lead plate. The authors consider that there are some penetrating particles present, though it seems possible that their absorption curves are not incompatible with a shower containing only electrons of fairly high energy. There seem to be some protons produced by nuclear interaction. The showers observed are probably part of large cascades produced by the multiplication in the atmosphere of an incident electron of very high energy. Assuming that this is so, the initial energy must be of the order $10^{13} - 10^{14}$ electron volts. It may be remarked that this is much larger than the energy which could be obtained by the complete annihilation of the heaviest atoms.

An Improved Liquid-Filled Prism

F. J. HARGREAVES has recently described his hollow liquid-filled prism of about 3½ in. effective aperture, the glass plates constituting the refracting sides of the prism being joined at their edges to the cell by goldbeaters' skin (*Mon. Not. Roy. Astro Soc.*, 99, 2; 1938). The object of this flexible connexion is to prevent stresses in the plates, each of which presses against external stops and is held there by the pressure of the dispersing liquid within the cell. A difficulty arose in supporting the weight of the glass plates, more especially as it is necessary to invert the prism to empty it. To prevent too much tension on the goldbeaters' skin supplementary support was provided by the use of slings made of phosphor-bronze wire. Another prism is under the process of construction on the same principle but with minor modifications in detail. The author sees no reason why much larger prisms should not be made on similar lines, though there is the difficulty of constructing large disks that are thin and homogeneous. Hargreaves thinks that this difficulty can easily be overcome.

The Structure of the Globular Proteins

By Dr. Dorothy Wrinch

ON recent occasions a number of objections to the cyclol theory have been raised, to many of which replies have already been given, explicitly or implicitly, in a number of publications, notably in Langmuir's lecture to the Physical Society on December 20, 1938¹. In view of the prominence which has been given to these criticisms, it seems desirable to summarize the replies.

It has been suggested that the number of theories such as the cyclol theory is so large that the *a priori* probability of any one is not sufficiently great for it to merit consideration^{2,3}. It is difficult to give much weight to objections of this type until it proves possible to formulate, or failing this to establish the existence of, a sufficiently large number of independent theories, each of which leads to structures accounting for the definite and discretely arranged molecular weights of the native proteins, their capacity to denature, to form spontaneously from solution highly insoluble monolayers and so on. So far as we are aware, no alternative structures have yet been proposed. Meanwhile, "the very large number of independent properties which are correlated by the cyclol theory and the extreme simplicity and the small number of postulates from which it is derived by purely logical processes"⁴, seem to give it a considerable *a posteriori* probability.

It is suggested that there are grave objections on chemical grounds to the postulate of the four-armed unit $>N-CHR-COOH<$ and indeed to the cyclol structure itself owing to the lack of precedent in organic chemistry for this diazine-triazine type of structure⁵. Proteins are so different from other substances that it is surprising that there is a reluctance to accept for them a structure for which no analogue in organic chemistry can be found. Globular proteins have not yet been synthesized in the laboratory. The fact that it has not proved possible to form ring structures from peptides⁶ is therefore scarcely to be regarded as evidence against the cyclol hypothesis. Furthermore, we would not regard the lactam-lactim tautomerism of peptides as the chemical basis of the cyclol theory⁴. At present, we do not know whether polypeptide chains constitute an intermediate stage in protein synthesis, nor is it clear that the cyclization of chains, if it occurs, entails the postulate of lactam-lactim tautomerism of peptides.

Further criticisms of the cyclol hypothesis are as follows: (a) the theory is incompatible with the findings of enzyme chemistry^{7,8}; (b) it cannot explain certain facts of denaturation⁹; and (c) it has not proved possible to synthesize in the laboratory certain "simple models of cyclol type"⁴, or to induce the formation of cyclol links between simple molecules⁴.

(a) In accordance with the current ideas in the kinetics of reactions, it was suggested by Langmuir¹ that there is a tautomeric equilibrium in the globular proteins between some of the four-armed units $>COH-CHR-N<$ and the two-armed units $-CO-CHR-NH-$, by means of which cyclol bonds are continually opening and reforming. Thus at any one time there

are some points at which a peptide link, $CO-NH$, can be attacked directly. The cyclol theory therefore does not, as has been suggested⁴, need to make the assumption that proteolytic enzymes open cyclol bonds. We know of no evidence which conflicts with the view that the enzyme can take advantage of the situation arising from the opening of these bonds, so that, if it is a fact that proteolytic enzymes act only on $CO-NH$ bonds, there is no incompatibility with the cyclol structure proposed for the globular proteins.

The objections (b) and (c) again raise the question of the nature of the cyclol bond. This bond in isolation may well be unstable; indeed the marked instability of the globular proteins in general and other considerations⁹ require it to be so. Failure to synthesize in the laboratory so-called "simple models of the cyclol type"⁴ (a phrase which may ultimately be found to be a contradiction in terms), or to induce the formation of isolated intermolecular cyclol links, is then no evidence against the cyclol hypothesis.

The stability of the globular proteins, under special conditions, in solution and in the crystal, we attribute to definite stabilizing factors^{7,8}; namely, (1) hydrogen bonds between the oxygens of certain of the triazine rings, (2) the multiple paths of linkage between atoms in the fabric, (3) the closing of the fabric into a polyhedral surface which eliminates boundaries of the fabric and greatly increases the symmetry, and (4) the coalescence of the hydrophobic groups in the interior of the cage. If these stabilizing factors are withdrawn the cage structure collapses. Denaturation on this theory (apart from the special type due to the dissociation of structures held together by hydroxyl or hydrogen bonds or salt or covalent linkages between *R*-groups^{10,11}), corresponds to any breakdown of the structure due to the opening of cyclol bonds^{4,12}. When few bonds are open they may re-form because of the multiple paths of binding holding the parts in position. Reversible denaturation (of either type) is thus not excluded by the cyclol theory. In the case of the fibrous proteins in which some cyclol bonds may be present,¹³ the first and second stabilizing factors may operate. The denaturation of myosin (which it is suggested is a difficulty for the cyclol theory⁴) thus seems to be easily interpretable.

The first stability factor also, it appears, may explain the fact that it has not proved possible to methylate or acetylate the peptide hydroxyls, which on the present hypothesis should be present in egg albumin and haemoglobin¹⁴.

It may be emphasized that whereas the first three stability factors are uniform for all the globular proteins, the strength of the fourth factor varies with the specific amino-acid composition of the individual protein. This point is demonstrated by the case of insulin, in which the exceptional behaviour (its resistance towards heat and acid, the stability of its crystals in the dry state, etc.) can perhaps be correlated with its abnormally high content of hydrophobic groups. The fact that insulin "cannot be denatured in the usual sense of the word"¹⁵ does not

provide evidence against the cyclol theory of denaturation: it illustrates the importance of the fourth stability factor. Incidentally, insulin, like many other globular proteins, spontaneously forms very insoluble monolayers from solution¹², a property which in itself indicates the likelihood of a cage structure^{1,13,14}. The spontaneous formation of monolayers from solution represents a very mild type of degradation, presumably involving no hydrolysis. It seems likely that much could be learnt about protein structure by studying the structure of the constituents of these protein monolayers. On the cyclol theory, fragments of fabric and closed polypeptide chains are to be expected when gentle methods of degradation are used which involve no hydrolysis¹⁵. The theory would not (as has been suggested⁴) make any predictions as to the nature of the products obtained when the usual gross methods of degrading proteins are used.

Other criticisms of the cyclol theory³ (dealt with in detail in other communications^{16,17}) relate to one particular point, namely, the suggestion that the insulin molecule has the cage structure *C*₁. It was shown at the outset¹⁸ that this structure satisfies the chemical and physico-chemical facts and also those relating to cell molecular weight, space-group and cell dimensions obtained in an X-ray analysis of a dry zinc-insulin crystal¹⁹. Controversy has, however, arisen as to whether it is consistent with certain vector diagrams of a dry zinc-insulin crystal published later²⁰. In view of authoritative opinions as to the inadequacy of the X-ray data²¹ (which make it highly uncertain how far the vector diagrams give even an approximately correct picture of the situation in the crystal) and as to the feasibility of making any deductions from such data in the absence of a chemical analysis of the crystal^{22,23}, it seems necessary at present to abandon the hope of reaching any final conclusion on this special point. Arguments can only revolve round the plausibility of subsidiary hypotheses.

THE GEOMETRICAL ATTACK ON PROTEIN STRUCTURE

It has been pointed out by Neuberger⁴ that many of the arguments in favour of the cyclol hypothesis could be used equally well in favour of any "regular geometrical structure which joins peptide chains to form a globular molecule", a theme which has already been developed in considerable detail^{24,25}. This remark, in focusing attention on the fundamental problem of protein structure, namely, the existence of megamolecules, puts into correct perspective the general investigations on protein structure of which those dealing with the cyclol theory form a part. These investigations have a wide scope. Given that protein molecules are polycondensation products of amino acids, interlinked by bonds between the nitrogen of one and the terminal carbon of another, there are only a certain mathematically determinate set of possible structures. The full and exhaustive formulation of these is the objective of this work^{24,25,26}.

Now the cyclol theory gives precise expression to this general point of view by postulating that these polycondensation products are built on the particular two-dimensional scheme exemplified by the cyclol network. No alternative comprehensive scheme has so far been forthcoming; but on the other hand, it has never been claimed that the cyclol pattern is the only design consistent with the chemical and stereochemical specifications²⁴. The characteristic

pattern must, of course, satisfy certain conditions; thus it must be such as to allow "the possibility of the regular and orderly arrangement of hundreds of residues"²⁴ (and herein lies the difficulty of attributing the fine structure of proteins to S-S, CO-S, NH-S or CO-NH-CO links as suggested by Neuberger⁴), and it must be capable of fragmentation into polypeptide chains. The cyclol postulate has been developed in considerable detail, since it was scarcely feasible to show the potentialities of the geometrical method by general statements alone.

It should, however, be recognized that there are broad deductions to be drawn from this point of view, irrespective of the particular form of the atomic pattern. Chief among these is the suggestion that the molecules of the globular proteins are cage-like structures, consisting of a characteristic fabric folded round to form a closed polyhedral surface^{13,27,28}. This simple corollary of the idea of a protein fabric, though in point of fact suggested by the cyclol hypothesis, is independent of this or any other postulate. Whether or not the cyclol hypothesis proves to be correct, it certainly establishes the existence theorem in the mathematical sense, proving that there are no intrinsic impossibilities in the cage type of structure, showing how the atomic pattern can determine size and shape, and proving also that the cages may be rendered highly specific by the conditions of linkage imposed on the individual atoms.

The present controversy—wholly concerned with details of the cyclol pattern—makes it clear that the determination of the atomic pattern of proteins is beyond the range of present chemical and physical techniques. It then seems all the more important to direct attention to this general issue as to the general nature of structures of the globular proteins. Whatever the atomic pattern may be, the fact remains that the defining characteristics of the native proteins not only fit in with the idea of a cage, but even seem to demand a structure of this kind for their molecules. On this point there seems indeed to be a growing consensus of opinion²⁴. In any case, the central problem is to explain the existence of very large but chemically and physically well-defined molecules. The idea of a cage structure has been offered for consideration, as an explanation of this striking fact. Is it not possible, by means of experimental techniques already available, to recognize a cage when we see one?

'Stump' Planting

AS regards modern developments of what is now widely alluded to as 'stump' planting, the method in all probability was first introduced to plant up new areas in connexion with the irrigated plantations in the Punjab plains, the species first utilized being the shisham (*Dalbergia Sissoo*). 'Stump' is really a misnomer; for the piece of the plant alluded to is a root and shoot or stem cutting. Its success and cheapness under certain conditions in the Punjab was striking, and this success has been repeated elsewhere in India, for example, in the Terai and Bhabar lands in the United Provinces, and in northern Nigeria in Africa with the same species.

But successful as has been the afforestation work with shisham stump planting, it has proved even more successful with teak in many parts of India, where artificial replanting or new afforestation work is being undertaken under certain types of condition. So valuable and cheap is the method that it has spread far beyond India, and interesting work has been obtained with stumps in the west coast and other forests of both British and French Colonies in Africa.

In the past there has been a good deal of controversy as to the best size (length and thickness) of the root and shoot cutting or 'stump'. An ordinary method of obtaining these for planting out purposes in both India and Africa is to sow seed in a nursery

and then root and shoot prune when one year old, leaving eight inches of root and one inch of stem. A. L. Griffith, the Madras sylviculturist, has now discussed an investigation into the best root length of stump to use when stump planting teak (*Tectona Grandis*) in areas having a general west coast type of climate (*Ind. For. Rec.*, New Ser., 3, No. 1. Govt. of India Press, New Delhi, 1938).

From the details of the localities given it is obvious that by "west coast" the author means the west coast of India and not the west coast of Africa. But the experiments here discussed will prove of equal use in the latter region, where the introduction of stump planting is of a more recent date. The climate had an average annual rainfall varying from 60 in. to 120 in., and elevations varying from the plains at the foot of the Ghâts up to 3,000 ft. The soils at all centres were light forest soils naturally well aerated. Briefly, Mr. Griffith carried out a series of experiments in different localities over a period of four successive years (1932-1935). His results may be summarized as follows: There are no appreciable differences in results, at the end of the first growing season after planting, from stumps within the root length range of 6 in. to 10 in.; but a root length of 4 in. gives definitely poorer results. It was also demonstrated that stumps of 0.7-0.8 in. diameter give appreciably better results than those of 0.3-0.4 in. diameter.

Intelligence and Birth-Rate

IN a paper entitled "Intelligence and Birth-Rate" read before the Industrial Section of the British Psychological Society on February 8, Dr. L. S. Penrose summarized the present position regarding differential fertility and the decline in intelligence alleged to be taking place in Great Britain. By examining the results of differential birth-rates within the community, he brings to light the trends of social selection that are taking place, and in doing so, he links together a number of facts not usually associated in considering these matters.

Although the general problems of a declining birth-rate, owing largely to the efforts of the Population Investigation Committee, are beginning to attract wide attention, the effects of a differential fertility upon the ability of the nation as a whole are far too little appreciated. Knowledge of the relation between intelligence and birth-rate, as Dr. Penrose says, is of great practical importance in "planning the conditions of an efficient civilization". Even the most critical writers have been compelled to admit the presence of some fall in national ability. Thus Prof. J. B. S. Haldane writes that we may "expect a slow decline perhaps of 1 or 2 per cent per generation in the mean intelligence quotient of the country". (*'Heredity and Politics'*, p. 117.)

The subject of a decline in the nation's intelligence is one that lends itself easily to sensationalism, and the presentation of Dr. Penrose is to be welcomed as a dispassionate and timely one. At the outset he points out that the fall in the birth-rate may be due to diminution in family size, which implies a larger

proportion of first-born children. Thus the average sibship in Great Britain now is said to be half of what it was fifty years ago.

Apparently, only in one type of mental defect, namely, that associated with lesions in the pyramidal tract, has Dr. Penrose been able to satisfy himself that primogeniture is a highly significant factor. But he admits the existence of evidence pointing to raised incidence, among the first-born, of abnormal confinements, still-births, and congenital malformations such as anencephaly, spina bifida and hydrocephalus. There is evidence also that first-born children more frequently tend to become problem children than the later born, though here other selective influences may be at work bringing the first-born children to the notice of the clinics. It has also been maintained that the first-born are more likely to become insane than the later born, and that the chances of being convicted of criminality are much greater in the first two members of a family than in the rest of the family.

Maternal age at the birth of a child is the next factor considered by Dr. Penrose. Where the birth-rate is falling, the average maternal age will probably become greater. Dr. Penrose estimates the average maternal age in England as 29 years; in Japan it is said to be 26 years. Maternal age is particularly significant in the etiology of mongolian imbecility, the chances of the occurrence of this kind of defect being more than doubled for every increase of five years after the age of twenty-five years. The chances of the birth of a mongolian imbecile before the maternal

age of 25 years are estimated by Dr. Penrose as about 1 in 6,000.

Other influences related to changes in intelligence level and discussed by Dr. Penrose are birth-rates in rural and urban populations. Fertility is higher in rural than in urban areas, and the average intelligence is generally found to be much lower in the country than in the towns. Actual mental deficiency is also found more frequently in rural than in urban districts. The main cause would presumably be the migrations of the more able people from the country to the town, where industrial development offers them greater economic inducement than is found in agricultural areas. An additional factor in the decline of fertility among certain classes has frequently been stressed. This is the high cost of education and general high standard of living. Yet another factor is the employment of women, usually the more intelligent ones, in industry and commerce.

Whatever effects social selection has upon the level and distribution of intelligence, it certainly seems to have favourable effects upon physique. Besides a marked reduction in the incidence of diseases like tuberculosis, a notable increase has taken place in the average height and weight of working-class school children. As regards the question of intelligence as an inheritable character, Dr. Penrose inclines to the

view that the presence of a favourable environment may make a significant difference to the scores made on an intelligence test.

Dr. Penrose leaves open the possibility of an I.Q. of 90 becoming normal with an improved environment. Some psychologists would consider this as somewhat too high an estimate of the possible effects of environment upon the scores of an intelligence test. He concludes that "on account of social selection, the intelligence level of the general community tends to move towards the point at which fertility is highest". He takes, however, a more moderate view of the point of highest fertility than other writers and regards it as lying in the region of 90 (Binet I.Q.). In his view the "fecundity of the mentally defective is largely mythical" and those with an I.Q. below 70 have a fertility about one quarter of the normal.

Finally, Dr. Penrose is inclined to believe that the most immediate causes of differential fertility and also of general trends in birth-rate are probably psychological in nature. In this connexion it might be worth mentioning that a very recent investigation of Prof. L. M. Terman on marriage revealed that orgasm inadequacy was present in one third of the women in his large sample. His analysis suggests that this inadequacy may be largely genetic in origin.

J. I. COHEN.

Protection of the Fauna and Flora of Africa

THE "Final Act" of the Second International Conference for the Protection of the Fauna and Flora of Africa, held in London in May last has now been issued.* The Conference was held under the chairmanship of the Earl of Onslow, and was attended by delegates of the following Governments: Union of South Africa, Belgium, Great Britain and Northern Ireland, Egypt, France, Italy, Portugal and the Netherlands. The interests of the Anglo-Egyptian Sudan were represented by the United Kingdom and Egyptian delegations jointly.

The delegates met, at the invitation of the Government of the United Kingdom of Great Britain and Northern Ireland, on May 17-24, the invitation having been issued in accordance with the terms of the protocol which formed part of the agreements concluded at the International Conference for the Protection of the Fauna and Flora of Africa, held in London in 1933. The Conference had before it a number of statements which had been circulated by delegations on behalf of the Governments represented, setting out the measures which had been taken in their territories to give effect to the provisions of the Convention.

The Act sets forth the names of the delegates and advisers of each Government represented; and a list of the committee of experts appointed to make suggestions for the addition of further species to the Annex to the Convention on the occasion of its next revision. Great Britain was represented by the Right. Hon. the Earl of Onslow, Sir William F. Gowers, Mr. E. B. Bowyer and Mr. B. F. Wright as delegates, and by Mr. T. Hoakyns Abraham, Captain Keith F. T. Caldwell, Mr. B. Cookram,

Captain J. G. Dollman, Mr. J. M. Ellis, Mr. G. G. Fitzmaurice, Dr. C. Forster-Cooper, Mr. Hugh Fraser, Sir Arthur W. Hill, Mr. L. W. N. Homan, Dr. Julian S. Huxley, Dr. P. R. Lowe, Sir Guy A. K. Marshall, Sir Peter Chalmers Mitchell, Mr. A. H. Stocks, and Mr. M. J. R. Talbot as advisers. The secretary-general was Mr. Francis Hemming, and the secretary, Mr. D. H. F. Rickett. It also reports the statements made by the various delegates, who briefly outlined the measures taken by their various Governments to give effect to the provisions of the Convention.

The Act is followed by eight annexes: (1) dealing with the report of the Committee of Experts relating to the species of mammals, birds and plants recommended for inclusion in the Annex to the Convention on the occasion of its next revision (pp. 38-69), and (2) memoranda submitted by the various Governments on the action taken by them to give effect to the provisions of the Convention (pp. 70-149).

The memorandum submitted by the Belgian Government (pp. 72-73) is followed by several enclosures (pp. 74-127) in which is set forth a full and complete exposé of a decree of April 21, 1937, on "La Chasse et La Pêche au Congo Belge", and a discussion of every article governing that decree and the motives which have suggested them. It is a very valuable contribution to the subject of international conservation of faunas and floras.

From the scientific, economic and biological points of view, the importance of the two African conferences which have already been held can scarcely be exaggerated, in that for the first time in history concerted international efforts have been made to ensure the preservation of the fauna and flora of an entire continent before it is too late.

* Second International Conference for the Protection of the Fauna and Flora of Africa, London, May 1938. Final Act. Pp. 149. (London: H.M. Stationery Office, 1938.) 2s. 6d. net.

For the first time in the history of the world, delegates of, and advisers to, the various Governments concerned have met together in council, armed with the knowledge and experience of the disastrous results which may follow the uncontrolled actions of blundering and profiteering man, in order to devise reciprocal measures designed to prevent such actions in the future and to conserve for all time, in so far as it is possible, the natural features and economic possibilities of a great continent.

It is true that as yet only the most elementary steps have been taken, but the important point is that a beginning has been made and definite steps in the right direction taken. Doubtless as more conferences are held, the necessity for enlarging the scope of the term 'flora' will be realized, until it comprehends the consideration of the far wider question of the preservation of the balance not only between forested and unforested areas, but also of the proper conservation of those essential areas which act like sponges for the storage of water and control the water supply of those areas of land

which can be properly utilized for agricultural purposes.

In this connexion, the deliberations and actions of future conferences will surely profit by the gross mistakes which were originally made in developing the agricultural resources of such countries as the United States of America, Australia and New Zealand. In America, for example, we now know that as a consequence of ignorant and thoughtless drainage schemes, thousands of square miles of good land have literally 'gone with the wind'; while in Australia the over-zealous clearing away of forested areas has upset the biological balance of Nature, with the inevitable and consequential appearance of various plagues of an animal or vegetable nature which may, and have, cost millions of good money to combat. We would venture, therefore, to make the suggestion that the work of future conferences would be enormously benefited and its scope very profitably enlarged by the inclusion in its general body of national advisers of a sufficiency of forestry experts.

PERCY R. LOWE.

The Morphology of the Carpel

AN important contribution to the vexed question of carpel morphology has recently been published in *La Cellule* (47, 287-452; 1938) by Prof. V. Grégoire, the late professor of botany at the University of Louvain (see *NATURE*, 143, 400; 1939); it is characterized by the remarkable number of fine illustrations, mainly photomicrographs (no fewer than 252 in fourteen plates). The problem is approached from the point of view of development, and it is more than a coincidence that both Prof. McLean Thompson, of the University of Liverpool, and Prof. Grégoire, approaching it from this angle, reject decisively the classical theory that the carpel may be regarded as a modified leaf. The "state of flowering" of McLean Thompson and the "reproductive apex" of Grégoire necessitate a new terminology to interpret their characteristics of form, as both authors are agreed that analogies from vegetative organizations are misleading and quite unjustified.

We owe to previous papers by Prof. Grégoire and his colleagues the concept of the vegetative growth apex as establishing, in successive time intervals, or plastochrones, a series of transversely expanded foundations, which are components of the axis (the *soubassements*), upon which are then raised new foliar primordia. This mode of growth necessitates a meristem organized in depth and constructed, in modern terminology, of a tunica overlying a corpus, both of which have a meristematic nature and contribute to these successive units of shoot organization.

Prof. Grégoire points out that neither tunica nor corpus can be identified at the reproductive apex. There is a superficial meristem of uncertain depth, covering both the summit and the flanks of the apex; but this is not identified as a tunica because of the frequency with which periclinal divisions alternate with anticlinal, thus adding to the depth of parenchyma below. Below it there is no meristematic corpus at all, but a parenchymatous mass homologous with the pith. The superficial meristematic layer can add no units of construction to the shoot; the floral parts are simply emergences from it with no axial founda-

tion such as is present with a leaf primordium. Not even the sepals are regarded now, in contradistinction to Grégoire's earlier views, as homologues of foliar structures.

The insertion of each new foliar primordium becomes the centre of a new impetus to procambial activity, the leaf-trace system of the new unit thus contributing basifugally to the vascular tracts spreading into the leaf and basipetally to the trace system linking this with the axis. In the reproductive axis, this basipetal contribution to procambial development is missing; from a procambial 'magma' often of considerable extent and sometimes spread solidly across the base of the reproductive axis, cordons of procambium, often anastomosing or bifurcating freely, spread basifugally into peduncles and then into floral parts; but there is no suggestion that this procambial activity contributes basipetally to an enlargement of the vascular system below the reproductive axis.

The two types of growth, the vegetative and reproductive, are fundamentally distinct and not reducible to a common plan. A reproductive apex does not even develop out of a vegetative apex by its gradual modification; it arises as a lateral growth on the side of the vegetative apex that it displaces, and if subsequent proliferation shows a return to foliar emergences then a vegetative apex has re-arisen adventitiously on a reproductive axis. Such a reproductive axis, always a layer of meristem tissue upon a parenchymatous plinth, still capable of some growth and extension (the *porte-méristème* of Grégoire) may be used up entirely in the production of floral parts, it may dichotomize by the development of a central groove, or divide into more fragments as the result of more grooves developing. Its floral members arise without plastochronic intervals and these members are local products of a portion of the meristem without the tendency to bilateral spread around the axis characteristic of the foliar primordium.

Grégoire distinguishes two types of carpels among those now described: the *Ramunculus* type, in which a

transverse or tangential slit separates a dorsal upcurving and enclosing segment from a ventral, or the abaxial face of which a single ovule arises in the median position; and the *Aquilegia-Rubus* type, in which a very narrow radial slit is present between two lateral walls, joined external by a strongly developed dorsal wall which runs up into the stigma. This type gives the follicle which is the basis of the foliar theory of the carpel, but Grégoire points out that the thin radial slit first formed does not agree at all with the concept of two incurving leaf margins joining to give the ventral suture. In the *Aquilegia-Rubus* type this thin slit later expands at its outer margin to give the cavity on which are formed the ovules, few in number but necessarily lateral in position, but in *Papaver*, *Butomus*, etc., the whole surface of the slit is meristematic and active in the production of ovules. Prof. Grégoire shows that perigyny is a natural development of the outer margin of the parenchymatous plinth upon which the reproductive meristem is carried; he thus excludes its interpretation as a concrescence of sepals. He emphasizes that from the new point of view perigynous forms are not to be interpreted as intermediate between epigynous and hypogynous.

The whole paper is a vigorous challenge to classical morphology in a field where there has been much activity in recent years. Prof. Grégoire refused to consider the palaeobotanical contributions to this problem and the cupule theory that has thus emerged; but apart from this there is a very full discussion of the bearing of his most recent observations upon the diverse interpretations that have been given to the carpel.

The S.S. *Archimedes*

IN March 1839, the historic little screw-driven vessel S.S. *Archimedes* began her trials in the River Thames. A month or two later she visited Portsmouth, and afterwards made voyages around the coasts of Great Britain and to Holland and Portugal. She was the first vessel to demonstrate effectively the suitability of the screw for ocean-going ships and she ushered in the revolution which led to the abandonment of paddle-wheel propulsion in the ships of both the Royal Navy and the Mercantile Marine.

The *Archimedes* was built of wood at Millwall by Henry Wimsurst (1804-84) for the Ship Propeller Company, a syndicate formed to further the use of the screw-propeller patented by Francis Pettit Smith on May 31, 1836. Smith had previously built a small screw-driven boat of 6 tons bearing his name. The *Archimedes* was 125 ft. long overall, 106 ft. long between perpendiculars, 22½ ft. beam and drew between 9 ft. and 10 ft. of water. Her tonnage was 240 tons. Her machinery consisted of a two-cylinder steam-engine driving the propeller shaft through spur gearing. The cylinders were 37 in. in diameter and 3 ft. stroke. With steam at 6 lb. pressure the engine developed about 80 horse-power. The engine speed was 26 revolutions per minute and the propeller speed 140 revolutions per minute. The first screw fitted was of 7 ft. diameter, 8 ft. pitch and 8 ft. long. This in 1840 was replaced by a double-bladed screw of 5½ ft. diameter, 10 ft. pitch but of greatly reduced length, but various other screw propellers were also tried. Her machinery was made at Greenwich by J. and G. Rennie. The total cost of the vessel was £10,500.

In accordance with Admiralty instructions early in 1840, Captain E. Chappell, who had been associated with the Steam Packet Service, took command of her and a series of trials were carried out at Dover between the steam packet *Widgeon* and the *Archimedes*. The *Widgeon* was 162 tons and was the fastest boat on the Dover station. The trials were attended by Thomas Lloyd, who afterwards became the first Engineer-in-Chief of the Navy. The joint report of Chappell and Lloyd dated May 2, 1840, was the first official report made to the Admiralty on screw-propulsion. In it it was stated that "it is evident in these vessels the power of the screw is equal, if not superior to that of the ordinary paddle-wheel. In this respect therefore Mr. Smith's invention may be considered completely successful." After some remarks on the noise and wear of the gearing, the teeth of which were of wood, the report went on to say that "It is, however, in propelling vessels of war that the value of Mr. Smith's invention will probably be experienced. . . . A ship fitted with a screw propeller may be used either as a sailing or a steaming vessel, or as both, if required; for we ascertained by experiment that the engine can be connected and disconnected with ease, and in any weather, in two or three minutes. In carrying a press of sail, the inclination of the ship does not diminish the propelling power of the screw nor lessen the ship's way, as with the ordinary paddle-wheel. The getting rid of the paddle-boxes also leaves the broadside battery altogether clear of obstruction, and in boarding an enemy's vessel would allow of the ships lying close alongside of each other".

Experiments with the *Archimedes* were also carried out at Bristol by Brunel, and it was through these that he was led to adopt screw-propulsion for the famous *Great Britain*, the first screw-driven ship to cross the Atlantic.

University Events

CAMBRIDGE.—The Jacksonian professorship of natural philosophy is vacant. The stipend of the professor is £1,200 a year or, while he holds a fellowship of a college with dividend, £1,000. The professorship is assigned for this turn to experimental atomic physics and will be associated with the Cavendish Laboratory. Candidates are requested to send their names to the Vice-Chancellor on or before April 11, 1939, with twelve copies of any statement or testimonial which they desire to submit to the electors.

The Smith's Prizes have been awarded to T. E. Easterfield, of Clare College and H. N. V. Temperley, of King's College; and Rayleigh Prizes to J. Corner, of Peterhouse, D. S. Evans, of King's College, R. A. Rankin, of Clare College and D. B. Schultz, of Magdalene College.

ST. ANDREWS.—Prof. E. Finlay Freundlich, formerly professor in the German University, Prague, has been appointed Napier lecturer in astronomy and director of the new Astronomical Observatory in the United College, St. Andrews. The lectureship owes its institution to a bequest made to the University by the late Miss Scott Lang, daughter of Sir Peter Scott Lang, formerly professor of mathematics in the United College. It was the desire of Sir Peter Scott Lang that the lectureship should bear the name of Napier of Merchiston, one of the early students of the University.

Societies and Academies

London

Royal Society (*Proc.*, A, 169, 451-590; 1939)

E. TOSATTI: Respiratory function of straight and crossed fibres in the anterior of the tract cervical chord.

Forthcoming Events

[Meeting marked with an asterisk is open to the public.]

Tuesday, March 21

ROYAL COLLEGE OF PHYSICIANS, at 5.—Prof. J. A. Gunn: "The Pharmacological Actions and Therapeutic Uses of some Compounds related to Adrenaline" (Oliver-Sharpay Lectures. Succeding lecture on March 23).

Friday, March 24

GEOGRAPHICAL DISCUSSION (at the Royal Astronomical Society) at 4.30.—"Recent Geophysical Investigations at Sea" (to be opened by Dr. E. C. Bullard).

PHYSICAL SOCIETY (at the Imperial College of Science and Technology), at 5.15.—Brigadier M. N. MacLeod: "Some Recent Developments in British Surveying Instruments" (Thomas Young Oration).*

INSTITUTE OF PHYSICS, March 23-25.—Conference on "Physics in the Textile Industries" to be held in the University of Leeds.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

ASSISTANT (grade II) in the Balloon Development Establishment, Cardington—The Under-Secretary of State, Air Ministry (S.2.D), Berkeley Square House, W.1 (March 24).

JACKSONIAN PROFESSOR OF NATURAL PHILOSOPHY in the University of Cambridge—The Vice-Chancellor (April 11).

LECTURER IN PHYSICS in the Battersea Polytechnic, London, S.W.11—The Principal (April 21).

No. 3621

Scientific and Industrial Research in Great Britain

WITH the increase in the number of reports issued by individual boards or departments under the Department of Scientific and Industrial Research, the value of the Department's own report, a survey of which appears on p. 499 of this issue, and especially that of the Advisory Council, is enhanced rather than diminished. Apart altogether from the broad picture it gives of the many-sided contributions made by the Department to the welfare of the whole nation, it has become increasingly a vehicle for the discussion of the more fundamental problems of co-operative scientific and industrial research, and of the factors upon which success or failure in this field depend.

An important section of the report of the Advisory Council is this year devoted to the position of the research associations, and this discussion is of the greater interest in view of the recently published report of the Parliamentary Science Committee on the Finance of Research (referred to in *NATURE* of January 28). Indeed it may be said that, taken as a whole, the report of the Department supplies a much more convincing answer to the arguments of that report than those in the observations of the Advisory Council on, and published with, that report. The practice of the Department is even more reassuring than the arguments advanced by the Advisory Council in defence of the policy upon which that practice is based. The straightforward narrative of the achievements of the Department contains encouraging evidence of flexibility and foresight, and some attempt to diminish those fluctuations of income which have such an adverse effect alike upon the conduct of long-range investigations and on the work of the staff responsible for their conduct.

Five years ago, the major part of the report of the Advisory Council was devoted to a historical

review of the research association scheme for developing the application of science by industry in Great Britain, and its criticism of the movement was directed to the inadequate scale on which it was financed. Recommendations then made for remedying this weakness were accepted by the Government, but subsequent discussions with the various associations led the Advisory Council to believe that to encourage them to embark on operations on a more adequate scale the basis on which grants were made must be definitely shaped with that primary purpose. Accordingly the Council recommended that the Department offer block grants of so substantial an amount that, with the contributions from industry upon which they should be conditional, they would secure an income adequate for each association to develop a really effective organization. To encourage further development, the Council recommended additional grants, on a sliding scale, within prescribed limits, on all income raised from industry in excess of a specified figure. The amounts of the minimum income, the specified figure and the limit of the grant were to be determined on the merits and needs of each case, and the normal period of these new arrangements was to be five years. The success of this plan is shown by an increase of nearly forty per cent in the total sum subscribed annually by industry on the amount provided before it came into operation, although it has to be admitted that that sum is still only a little more than a quarter of a million pounds.

The Advisory Council has now again reviewed the whole position, and arrangements have been made by which consideration of individual research associations will be spread over several years, thus keeping the general scheme under inspection and securing a thorough periodical examination

of each individual association. It is proposed to make a detailed review of the work and progress of each association at the end of the particular five-year period for which its grant has been made, before recommending grants for a further period.

This arrangement has brought under review in the present report the Wool Industries Research Association and the research association of the iron and steel industry. Grants have also been made to the newly formed British Coal Utilisation Research Association. The comments in the report of the position of these and other associations deserve some note as indicating some of the general tendencies and weaknesses of the research association movement.

It will be remembered that in observations on the memorandum of the Parliamentary Science Committee on the Finance and Development of Research, the Advisory Council reiterated the view which was expressed in its report for 1930-31 that the expenditure on research which is defensible in the national interest depends on the degree to which industry generally is prepared to apply scientific method and advances in scientific knowledge. The position of the Wool Industries Research Association illustrates the limitations and defects of that method. The admirable work already conducted at Torridon, with the light which it has thrown, for example, on the fundamental structure of animal fibres, has earned for the Association a high scientific reputation, and the fundamental knowledge and technique thus acquired have found application in fields well beyond the bounds of the woollen industry. It cannot accordingly be regarded as entirely satisfactory that such important contributions to the general body of scientific knowledge should be retarded by the failure of an industry to appreciate the importance of research.

It is, of course, realized that only an industry that is thoroughly research-minded can be expected to support such fundamental research, the bearing of which upon manufacturing technique or development is not immediately apparent. If, however, there is any force in the contention that fundamental or long-range research is pre-eminently the field of the research association, as distinct from the research departments of individual firms, the present policy of the Advisory Council has obvious limitations and design. That this is realized by the Advisory Council is indeed shown by its own recommendations in regard to the British Boot, Shoe and Allied Trades Research Association.

Failure of this Association to obtain and maintain an industrial income of only £7,000, which would have secured a total income of £12,000, led to it operating for two years without a grant. Impressed by the special limitations in the field of work open to this Association, owing to the almost complete monopoly in the supply of machinery to the industry, and in view of the importance of shoe-efficiency to the national health, the Advisory Council as an exceptional measure has recommended an offer of renewed grant aid which will secure for the Association a minimum income of £8,000 a year with a possibility of £12,000.

In a recent letter (*NATURE*, 143, 336; Feb. 28, 1939), Dr. W. H. Gibson stressed the importance of consideration of the position of research associations in a scientific spirit, and directed attention to some of the limitations which are commonly imposed on their work. If they are to confine themselves to research on the processes of their members, they will be limited in their work essentially to those fields which are the natural territory of the research departments of the individual firms. This means further limitation of the fundamental research which is the basis of all major industrial advance, but which is often beyond the resources of all but the very largest of industrial units, and indeed it may be added, is often a tax upon the resources of the best-equipped university departments, to which alone we can look further for assistance. It may be noted that the large industrial firms often prefer to support such investigations by specific grants to a university department rather than to embark on them in their own laboratories.

Even, however, if we could safely rely on the universities for the fundamental research which is required for the advance of industry—and there are very definite limits to the extent to which research at a university should be dictated even by national needs, let alone the requirements of industry—it is obviously unreasonable, if not impossible, to expect them to provide for a further need to which Dr. Gibson directed attention. Dr. Gibson stressed the importance of research upon the raw materials themselves, the price of which often constitutes a large proportion of the price of the finished article. Unless and until attention is paid to ensuring ample supplies of uniform quality and reasonable price, no amount of research on processes will overcome the difficulties of British industry.

Equally important is research in developing entirely new uses for raw materials outside existing

channels. Many notable advances have originated from the use of some raw material for a new purpose. Under present conditions, a research association which is working for members who are operating established processes cannot embark on such investigations. Accordingly a most fruitful field lies neglected and unfinanced.

As we have repeatedly urged in these columns, what is required is a scientific approach to the whole problem, and the orientation and distribution of the national research effort in accordance with a comprehensive survey of the resources available. This is essential, apart altogether from the question of the magnitude of the total effort or even of the relative contribution of industrial or national sources. Only as we can assess with some degree of accuracy the contribution which is being made in different fields and from different sources can we make any sound decision as to the magnitude of the contribution which should come from the national revenue. The observations of the Advisory Council on the position of the research associations emphasize the need for this comprehensive survey and for some attempt to delineate broadly the field between the various research organizations—private enterprise, research associations, Government research stations and the universities.

An authoritative survey of this type could scarcely be undertaken except under Government initiative and authority, although it is possible that something on these lines might come within the field of the newly formed Division for the Social and International Relations of Science of the British Association. At least it might facilitate the scientific approach to the problem which is badly needed, and the enunciation of principles upon which increased Government grants for scientific research could be indubitably justified, whether to the universities themselves, to Government research stations or institutions or to the research associations.

A step of this kind should not be without effect on a further aspect of the situation to which Dr. Gibson also directed attention—the position of the scientific worker. The great divergencies which exist between the position of scientific workers engaged in essentially similar duties in the universities, Government establishments, private firms and research associations are not to be defended. Co-operative research associations which are supported in part by an industry are at a disadvantage in retaining an experienced staff as

compared with an industry which for some reason or other may make no contribution towards co-operative research, either getting it done by a Government establishment or relying on individual and private effort. The results achieved in co-operative research depend not merely on the financial resources at the disposal of the research associations but also on the calibre of their scientific and technical staff. If the conditions of service are so inferior in remuneration or security to those which obtain elsewhere that they cannot compete on equal terms with private industry or Government departments in recruiting their staff, the quality of their work must ultimately be lowered.

The importance of this question to the industries concerned, no less than to the nation itself, need scarcely be stressed in view of the past achievements of the research association movement. It deserves closer attention than it has yet received from the professional associations of scientific workers, and any comprehensive survey and analysis of the research effort of the nation should have reference to this problem also. It should not be forgotten, of course, that mobility of staff within limits has its own advantages in stimulating the exchange of technique and ideas. A definite drawback of pension schemes is in fact the indirect discouragement which they give to the movement of staff, and there are other factors which in recent years have discouraged the movement of scientific workers from one firm to another, whether within the same industry or not. Such movement may be stimulating in ideas and technique as well as facilitating the growth of a wider judgment or experience of great value in the direction of research in industry and Government service.

A more liberal policy in regard to the exchange of pension rights might well prove a sound investment both to Government services and industry, and it should not prove beyond the national resources to devise some means of eliminating that factor of insecurity of tenure which in other fields of research besides that of the research associations tends to affect adversely the recruitment of scientific staff of the highest quality. Certain it is that if the research association movement is to find a definite place in the national organization for research, it will only make its full contribution if the same careful consideration is given to the broad fields in which it should operate, and to the conditions of recruitment and employment of its scientific and technical staff, as has been given in the past to the assessment of its financial grants.

Vitamin B₁ and Scientific Endeavour

Vitamin B₁ (Thiamin) and its Use in Medicine
By Dr. Robert R. Williams and Prof. Tom D. Spies. (Macmillan Medical Monographs.) Pp. xvi + . (New York: The Macmillan Co., 1938.) 21s. net.

"IT is doubtful whether the isolation and identification of any other substance in the history of biochemistry have cost as much labor as have these operations as applied to thiamin. The first gram of the pure vitamin must have cost an aggregate of several hundred thousand dollars. To mention all the names of those who have participated in some phase of the project is to call the roll of half the mature biochemists in England and the United States. The project has bulked equally largely upon the horizon of Dutch, Japanese and French Biochemistry. German participation has been relatively small until the current decade."

"One could be pardoned for hoping that a knowledge of the chemical structure of thiamin would promptly suggest the mode of its action and resolve many of the problems that have plagued us for a generation. The natural processes into which it enters are, however, so complicated that for the present at least this knowledge only opens up a vista of new problems. The progress of the past year has been such as to justify the optimism for the future, but the gratification of our most sanguine hopes must be deferred for a time."

VITAMIN B₁ is now the most important of a group of vitamins constituting the original vitamin B. These opening paragraphs to two of the chapters in this book indicate the magnitude of research effort in connexion with this one chemical substance, as well as the task set themselves by the authors; to this must be added that they have tried to make available the present knowledge in practical medicine. Of this value there is at the present time no doubt; as well as a complete cure of the disease of beriberi, we know that in neuritis of various origins (especially alcoholic) and other conditions, there may be involved a factor of vitamin B₁ deficiency. Even in pellagra, in which the mouth and skin symptoms are now known to be cured by nicotinic acid, nervous symptoms are found to respond to vitamin B₁. The pyrophosphoric ester of this vitamin, the so-called co-carboxylase, is essential in the production of the precursor of alcohol (acetaldehyde) in alcoholic fermentation from pyruvic acid. There is an element of romance which defeats the scientific approach when we realize that this very vitamin, which is responsible for the production of the alcohol in wines and spirits, must be administered to protect the subject from the neuritis due to excessive indulgence

in the alcohol so produced! In the nervous system as elsewhere, vitamin B₁ is required for the degradation of pyruvic acid, which forms an essential stage in metabolism of carbohydrate and may be concerned in one intermediary stage in the formation of fat

The tale which is told by the authors is viewed in the first instance as a problem in practical medicine and in the construction of diets which may be needed to save from the consequences of vitamin B₁ deficiency even in its milder forms; the conclusions here reached indicate that 1-2 mgm. of the vitamin are needed per diem to ensure health, and should do much to displace a facile optimism that the eating of an ordinary mixed diet is enough to ensure health. A particularly valuable feature of the work is the inclusion of the tables of the vitamin B₁ content of foods; these will form a basis for future research. This section of the work, in which Dr. Williams has had the advantage of Dr. Spies's present practical experience of nutritional deficiency, should be read by all those who are responsible for the maintenance of the health of the community, as well as being a guide in practical medicine.

The more medical part forms eight out of the twenty-nine chapters, the latter two-thirds of the book being devoted to the chemical nature and mode of action (biochemical and physiological) of this vitamin. In the final efforts to reach the constitution and synthesis, there is no doubt that Dr. Williams's discovery of the cleavage produced by sulphite was one of the major factors in chemical advance. Nevertheless it is interesting to reflect that there was a happy fitness in his successes; Dr. Williams's work started in 1912, and the final synthesis of the pyrimidine-thiazole compound by several people independently only took place some eleven years after the first isolation of practically pure crystals by Jansen and Donath. This was because the problem had not become one in pure organic chemistry until shortly before the end, even in spite of the international co-operation mentioned in the initial paragraph. Labels may be said to be rapidly disappearing in science as the boundaries of discipline become more fluid, but no group of workers can feel particularly conceited when the finish of their own work still leaves untouched so many essential problems. It has been seen that one prominent function of the vitamin (or of its esters) is decarboxylation. For the true insight into the mechanism by which this is effected we

may have to wait until a deeper knowledge of the structure of the atom is available; it is certain that the organic chemical structure does not enable us to predict the reason why the molecule (as the diphospho-ester) decarboxylates in yeast, but in higher organisms requires a simultaneous oxidative process.

The tale of the various functions of thiamin in Nature, its need for the growth of micro-organisms, and of the work which has led to the present ideas of the intimate connexion with carbohydrate metabolism is well told, with due caution and criticism and not without pointers for the future. It is a safe generalization, to which there is not much exception, that wherever there is life some form of this vitamin is a necessity. To this extent the original idea implied by Funk in the term 'vitamin' is now justified. Upon nomenclature

there is still some controversy, perhaps not very important. To many it will be difficult to dissociate their minds from the term 'vitamin B₁'. Others think with justification that the name 'aneurin' should be used as it was proposed by Jansen, the first to isolate crystals of the vitamin. Dr. Williams adheres throughout to the sombre 'thiamin', used by the American Medical Association.

The reviewer has nothing but praise for this work as a whole, for the knowledge which it displays, for its fair judicial outlook, and for its production. He has not detected many errors. One might be mentioned: the work of Carter and Drury, mentioned on p. 211, actually preceded that of Drury, Harris and Maudslayi. The publishers also deserve congratulations upon a high standard of production. R. A. PETERS.

Brighter Optics

(1) Introduction to Physiological Optics

By Prof. James P. O. Southall. Pp. x + 426 + 3 plates. (London, New York and Toronto: Oxford University Press, 1937.) 21s. net.

(2) The Science of Seeing

By Dr. Matthew Luckiesh and Frank K. Moss. Pp. viii + 548 + 1 plate. (London: Macmillan and Co., Ltd., 1937.) 25s. net.

(1) **E**NGLISH-SPEAKING scientific workers already owe much to Prof. Southall, since it was he who edited the English translation of Helmholtz's great work on physiological optics. Prof. Southall's aim in the present volume is to give his readers a general introduction to the broad science of light and vision which, without being too prosaic, would be accurate and trustworthy so far as it goes. Every observation dealing either with the physiology of the eye or with its optical properties found a place in Helmholtz's "Physiological Optics". It was, in fact, a text-book describing the normal working of the organ of sight. Only a rare genius like Helmholtz could make himself a master of both aspects of the subject, and since his time there has been a widening gap between them. It is doubtful whether the term 'physiological optics' is to-day a sufficiently descriptive title for a book on vision.

The chapters on the optical system of the eye, correction eyeglasses, and the movements of the eyeball are of a high quality. The author is here on firm ground and his literary style is quite crisp, but his treatment of the subject, although

comprehensive, is not elementary. The first chapter to deal with optical questions ignores thin lenses, and plunges almost immediately into a formal statement of the geometrical optics of thick lenses—a very specialized subject.

The treatment of the biological aspects of vision is far less satisfactory. Workers on the physiology of the eye have tried hard during the last ten years to free the subject from the dogmas which in the past have brought on it such discredit. Relics of the past persist, however, for, in answer to an examination question, "State the main facts of colour vision", nine out of ten students will begin their answers, "There are two rival theories of colour vision . . ." Much has been done to improve this state of affairs, and it is a great pity that Prof. Southall has not referred to the works of Adrian, Ames, Granit, Hartline, Hartridge, Stiles and others; Fincham is classed as an "also ran".

In parts the author is grimly determined not to be dull:

"a sprightly disposition is mirrored in an active pair of eyes that are incessantly darting this way and that. . . . Such eyes can speak all languages and need no interpreters. A downcast look, a scornful glance, a soulful gaze, these and many similar expressions are in common use to describe this interplay of the eyes which conveys so much meaning not only in the intercourse of human beings with each other but also between man and beast. What can be more beautiful and expressive than the eyes of a dog watching intently his master's slightest gesture."

(2) Prof. Southall has covered a very wide field dealing with visual problems, and it is surprising that so much is left over that Dr. Luckiesh and Mr. Moss can still find enough material to fill another large book about the eye, this time dealing with the practical aspects of vision and illumination. It is a great pity that there is such a sharp distinction between two aspects of the same subject as exemplified by these two books, for the problems are basically the same. "The Science of Seeing" is much the most serious book to be written by Dr. Luckiesh and his collaborator. Dr. Luckiesh is the director of the lighting research laboratory, General Electric Company, Cleveland. For many years he has been urging us to raise the level of artificial illumination. He does not believe in half measures. The existing level of domestic artificial illumination lies between 1 and 10 foot-candles. Dr. Luckiesh says:

"Similar measurements applied to various visual tasks in homes, schools, offices and factories indicate that hundreds and even thousands of foot candles are necessary even to reach the conservative standard of visibility adopted for the present purpose of demonstrating the use of the visibility method of prescribing foot candles on a rational basis. Engraving and sewing require 500 to 3,000 foot candles" (p. 343).

Illuminations of this order would render rooms so

hot that they would be uninhabitable unless a special cooling plant were installed. One is always a little surprised when those interested in high illuminations advocate their use for the good it does our eyes, whilst at the same time disclaiming all responsibility for the harm the resulting high temperatures would do to the rest of the body. It is to be hoped that interested parties will not wreck an admirable campaign for better artificial illumination by attempting to advance too quickly.

Illuminating engineers have received little support from biologists interested in vision, and one cannot blame Dr. Luckiesh and Mr. Moss for attempting to fill some of the gaps in our knowledge. They claim, for example, that the heart-rate is reduced to its resting level more rapidly when reading under an illumination of 1 ft. c. than when reading under 100 ft. c. Since the authors claim that the speed of reading was much the same under the two illuminations, most people might be forgiven for wishing to perform a given task under the lower illuminations, thereby saving some unnecessary heart-beats. For restful conditions in the home it would seem necessary to have low illuminations.

It is clear that the 'science of seeing' has not advanced far: 'physiological optics', although growing fast, appears to be not yet strong enough to give a helping hand.

An Encyclopædia of Music

The Oxford Companion to Music

By Dr. Percy A. Scholes. Pp. lv+1091+179 plates. (London, New York and Toronto: Oxford University Press, 1938.) 21s. net.

MR. WELLS'S "World Encyclopædia" has not, as yet, materialized, but encyclopædias and dictionaries are now appearing which, if they do not show that unity of plan which should dominate the work that Mr. Wells has in mind, may yet be regarded as its precursors. The "Oxford Companion to Music" conceals, under its modest title, a vast amount of learning, set out in orderly and scholarly fashion, and designed to provide clear and exact answers to the thousand-and-one questions raised by any inquiring and intelligent amateur of the art. It would be idle to expect to find, even within the compass of nearly eleven hundred large octavo pages of small print, detailed treatises on harmony, counterpoint, singing, the pianoforte, the organ, and so forth. But Dr. Scholes does better. He gives succinct accounts of the fundamentals

of the technical side of the art, sufficiently detailed to give the reader a firm grasp of the elements of the subject, and in many instances provides pointers which show where further information may be obtained.

It is difficult, within the compass of a short notice, to indicate adequately the scope of the information given in this truly encyclopædic work. As was to be expected, nothing of importance on the technical side has been omitted. Over and above this, one finds scholarly articles on such diverse topics as music-halls, hymns and hymn tunes, mis-attributed compositions, "God Save the King", concerts and concert halls, the printing of music, the profession of music, and the like. Analyses of the plots of the classic operas are provided, and the work abounds in biographical details. The scientific articles are brief but adequate—the article on acoustics being a model of its kind. Wherever possible, the treatment lays stress on the evolutionary aspect of the subject, and Spencer's definition of evolution as a change from

"an indefinite incoherent homogeneity to a definite, coherent heterogeneity" receives more than one illustration.

The author has a light touch, and his handling of some topics (see the article on absolute pitch) becomes easily conversational without in any way becoming discursive. It must not be assumed that the author has been unmindful of Lealie Stephens's warning—"No flowers, by request"—to contributors to the "Dictionary of National Biography", but the fact remains that his treatment of many topics is so thoroughly absorbing, so admirable an example of the art that conceals art, that there is a danger of the book's becoming a pleasant fireside

companion rather than a volume for the reference shelves.

The author has consulted experts in many friends, and has done so in the true spirit of Boswell, receiving the corrections with deference, but not always agreeing with them. He is to be warmly congratulated on the completion of a single-handed effort the magnitude of which cannot often have been equalled or exceeded.

The book is admirably produced, is profusely illustrated, and should indeed prove to be a Good Companion to all lovers of the art of music. But why omit all mention of Sims Reeves?

A. F.

Plant-Life of the French Mediterranean Region

La distribution géographique des végétaux dans la région méditerranéenne française
Par Ch. Flahault. Œuvre posthume publiée par H. Gausson. (Encyclopédie biologique, Vol. 18.) Pp. xi+180+4 plates. (Paris: Paul Lechevalier, 1937.) 100 francs.

BOTANICALLY the Mediterranean region is one of the best defined of the larger floristic and ecological divisions of the earth's surface. This is because of the high constancy of the seasonal distribution of temperature and rainfall maxima and minima. Data are not yet sufficient for an adequate survey of the whole region, which includes considerable parts of southern Europe, northern Africa, and western Asia, but the work here noticed is a valuable contribution to such a survey, in that it brings together especially the results of the author's numerous studies of the plant-life of a very typical and well-worked area of the western Mediterranean Basin. The work is published posthumously, since Flahault died in 1935, and was awarded the Gay Prize in 1937 by the Paris Academy of Sciences.

Much of the book is naturally concerned with details of the distribution of species and vegetation in the south of France, but many broader discussions and comparisons are included. The flora of the French Mediterranean basin is said to include about four thousand species of vascular plants; but a considerable number of these have a wide distribution extending far beyond the limits of the Mediterranean region. The interesting question of 'characteristic' species is discussed at some length. The high value which has been assigned to the olive as the sole or main indicator of the limits of the Mediterranean region (in France) is disputed on strong grounds. It is concluded that "le Chêne vert"

(*Quercus Ilex*) "est partout, dans le bassin française de la Méditerranée, où règne le climat méditerranéen; il est partout où se développe la flore méditerranéenne dans les limites du bassin. Il est le terme principal d'une association de végétaux qui caractérise la région méditerranéenne, mieux que tout autre caractère."

The limitrophic regions (of the halophytes, mountains, etc.) are briefly considered, and the French Mediterranean region proper is divided into three sectors as the result of a very full analysis of environmental conditions and their correlation with characteristic species and types of plant communities. Four maps form a valuable aid to a clear understanding of the text. One of the maps, particularly well printed in a wide range of colours and coloured patterns, shows the distribution of the main communities.

The influence of man on the existing flora and vegetation of the area is considered to be limited. The conclusions reached are exceedingly interesting, partly because they differ in some respects from those of other workers in other parts of the Mediterranean region. Thus Flahault definitely says that man has not profoundly modified the flora, even with reference to forest species; that man has unintentionally caused the extinction of relatively few species; and that man has introduced very few species which have become naturalized to the extent that they would survive in competition with the native plants were the human 'protecting' conditions removed. Naturally occurring species survive destruction, for at least very long periods, by a kind of passive resistance. Man's 'troubling of nature' is ephemeral, even in a country of ancient civilization, and Nature necessarily regains her rights as soon as the modifying agent is removed.

W. B. T.

Social Ecology:

a Critical Analysis. By Milla Alasa Alihan. Pp. xiii+267. (New York: Columbia University Press; London: Oxford University Press, 1938.) 14s. net.

THE author discusses theoretically the use of the concepts of plant biology in considering human phenomena. The advances made by the human sciences in recent years may be attributed largely to the introduction of biological methods and ideas into these studies. Human ecology is an extension of this principle. It has been defined as "the study of the spatial and temporal relations of human beings as affected by the selective, distributive and accommodative forces of the environment".

The so-called ecological school in the United States is still, apparently, in the stage of clarifying its fundamental concepts and has, so far, little experimental work to show.

The present work is largely a commentary and exposition of the principles laid down by the pioneers of human ecology in the United States such as Park, Burgess, McKenzie and others. The author's discussion might well have been more critical.

Writers in Great Britain like Hogben frequently stress the need for a planned ecology of human life, while Pearl, Charles and others have discussed population problems in the light of animal and plant ecology.

There is no doubt, as the author shows, that a great deal of light can be thrown upon human life by the use of ecological concepts such as concentration, centralization, segregation, invasion, zonation and so on, which also enable us to study social phenomena of a new type. Psychologists may, however, query the validity of postulating fundamental principles such as competition as the motive force in the formation of a community or natural order. Perhaps the rather novel way in which competition is defined, namely, in the sense of mobility, freedom of movement or independence of locomotion, makes the idea more acceptable, though it might be equally appropriate to identify 'freedom of movement' with a co-operative community instead of with a competitive one as the ecologists do. J. I. COHEN.

The Hills of Lakeland *

By W. Heaton Cooper. Pp. xviii+126+52 plates. (London and New York: Frederick Warne and Co., Ltd., 1938.) 15s. net.

THOSE who know and love the Lake District will like this book: those who do not know the former can learn to love it through the latter. The text is obviously from the pen of one who has learned to love his native Lakeland. He describes the past and the present of a gam of English scenery in a style so facile and clear that the reader is transported as in a dream through crags and fells that alas have never been seen by many. He pays justifiable tribute to a region of great natural beauty and leaves the reader with a longing to down tools and indulge in the dream he has created. The dream, too, often amounts almost to reality through the beautiful illustrations which adorn the text. There are sixteen plates in

colour and thirty-six plates in monochrome which have been executed by the author. These pictures make the book.

To realize and appreciate the majesty of Lakeland it is essential to know its past history. Therefore, the author describes well its geology, with the aid of maps.

Well-produced and beautifully illustrated books of this kind can do as much as, if not more than, any other form of propaganda to encourage appreciation and preservation of our natural heritage—the countryside.

Newer Methods of Volumetric Chemical Analysis

By Erna Brennecke, N. Howell Furman, Hellmuth Stamm, Rudolf Lang and Kasimir Fajans. Wilhelm Böttger, Editor. Translated by Prof. Ralph E. Oesper. Pp. xiii+268. (London: Chapman and Hall, Ltd., 1938.) 18s. 6d. net.

ALL who make any considerable use of volumetric analysis will find this monograph of great value, for not only does it treat of the most recent advances but also, in addition, the editor has secured the co-operation of a number of recognized experts to deal with the various sections of this symposium. The topics discussed are: (1) The elimination of the titration error in acidimetry and alkalimetry; (2) ceric sulphate and (3) alkaline permanganate as volumetric oxidizing agents; (4) iodate and bromate methods; (5) chromous solutions as volumetric reducing agents; (6) oxidation-reduction indicators and (7) adsorption indicators.

In each section there is an excellent blend of theoretical and practical exposition, while to each chapter there is appended a selected bibliography which includes papers up to the end of 1936. The monograph has been excellently translated from the second German edition and is well printed and produced.

The Lyre-Bird:

Australia's Wonder-Songster. By R. T. Littlejohns. Pp. 12+30 plates. (Sydney and London: Angus and Robertson, Ltd., 1938.) 4s. 6d.

TO take motion photographs in heavy forest successfully is no easy matter, and Mr. Littlejohns and his collaborator, Mr. A. H. Chisholm, would have had to give up the attempt if they had not received assistance from the Federal Government. The final result was an excellent sound film which the Government now uses for propaganda purposes.

Mr. Littlejohns has written an interesting account of the lyre-bird and has supplied to the different 'cuts' from the film appropriate letterpress. From these serial pictures we see that the tail, when in full display, is spread forward over the back in the shape of a fan, with the two lateral feathers at right angles.

The lyre-bird is also a fine songster, and in its mimicry is unsurpassed. It has been known to copy the notes and calls of no fewer than seventeen different species, and other sounds as well, such as the tearing of bark by black cockatoos.

Science in Industry*

THE twenty-third report of the Department of Scientific and Industrial Research, which covers the period October 1, 1937–September 30, 1938, includes the report of the Committee of the Privy Council signed by Lord Runciman, and the longer report of the Advisory Council over Lord Riverdale's signature, together with summaries of the work of the National Physical Laboratory and other research stations and research boards and brief accounts of the work of the various research associations. Like previous reports of the Department, the present one gives a most impressive picture of the immense contribution which the work of the Department is making not only to almost every type of industry but also in all aspects of national life.

The expenditure of the Department in 1937–38 was £872,127 gross or £637,200 net as against £583,230 net in 1936–37. As usual, the largest single item of expenditure was £110,907 on the National Physical Laboratory, compared with £105,589 in 1936–37, the gross expenditure of £252,209 including the cost of work at the Laboratory for the Food Investigation Board, the Radio Research Board, the Road Research Board and other research boards of the Department. Against this gross total, receipts amounted to £141,802, of which £69,822 represents fees from industry for paid work. The total receipts from industry, including contributions to co-operative research, amounted to £98,452 as against £106,250 in 1936–37, while a further £81,923 was received from other Government Departments for services rendered, £33,337 from the Road Fund for the road research and £6,282 from the Empire over-seas for food investigation. Expenditure on fuel research was £103,240 gross or £94,782 net, on building and road research £97,382 gross or £40,626 net, on the Chemical Research Laboratory £23,340 net, on food investigation £54,709 gross or £45,307 net, on forest products research £38,841 net, on water pollution research £9,134 gross or £5,421 net and on the Geological Survey and Museum, £71,472 net. Grants to research associations, etc., amounted to £148,282, as against £120,510 in 1936–37 and £108,951 in 1935–36, and the report notes the formation of a new research association, the British Coal Utilization Research Association, bringing the number of such associations to twenty-three.

The report refers to the dissolution of the

Radium Beam Therapy Research Board, but the investigation for which it was responsible will be continued under the general control of the Committee of the Privy Council for Medical Research, and the Department will continue to keep in touch with the physical investigations included in the general programme of research. The Welding Panel of the Steel Structures Research Committee has also been discharged during the year upon the completion of some outstanding work, as well as the Standing Conference on Timber Utilization.

Food

A large part of the report of the Advisory Council is devoted to a review of progress in food investigation in recent years. The food investigation organization of the Department has now completed twenty years of work, and under present conditions the work that was begun in the face of a serious shortage of food has lost nothing of the national importance which was attached to it in 1937. Indeed, questions of storage no less than of transport of food are now regarded as an essential, if not a decisive, element in a national policy of defence, and the importance of this phase of the Department's work to the whole community need not be further stressed. From the start, this work has been concerned to avoid loss and wastage, during handling and storage, in the supply of foodstuffs and to ensure that this supply is made available in the best condition. Throughout the period, the need of the consumer has been the governing consideration, and the Food Investigation Board has found solutions for all three of the great problems which confronted it at the start.

The problem of the preservation of fruit, much of which responds badly to ordinary cold storage, has been solved by the development of 'gas-storage', a new method in which the ventilation of cooled stores is adjusted so that their atmosphere contains just the right amount of carbon dioxide. Ten years ago there were no gas-stores. To-day they provide three million cubic feet of storage, and this is only a beginning. Again, up to 1933, Australia and New Zealand still had to send their beef to Great Britain in the frozen state, when it is not a satisfactory product. Now it has been shown that chilled beef can be preserved for long periods in special chambers enriched with carbon dioxide, and in 1937 Australia and New Zealand sent us some three quarters of a million hundred-weight of chilled beef carried in this way.

* Department of Scientific and Industrial Research. Report for the year 1937–38. (Cmd. 5937.) Pp. iv+203. (London: H.M. Stationery Office, 1939.) 3s. net.

The third problem, that of handling and preserving fish, which is highly perishable, and as ordinarily handled and stowed cannot be kept really fresh for more than ten to twelve days, has also been solved by the development at the Torrey Research Station of brine freezing and cold storage at a low temperature. By the new methods lemon soles have been stored for two years and were in excellent condition at the end of that period. Success in these fields has been achieved, as the Advisory Council's report insists, by building up, however slowly, a science of the storage and transport of food, and the achievements of the Department in regard to food investigation are a remarkable tribute to the service which science can render in everyday life.

The present report refers to other work in progress, including investigations of the changes in muscle post mortem, the rancidity of edible fats, the causes of rotting of eggs, the factors which affect the composition and structure of the fatty and muscular tissues of the pig and the quality of the bacon which depends upon them, the distribution of vitamin A in fish, the cold storage of herrings, the spoilage of haddock in crushed ice and chemical indexes of freshness. The work on gas-storage has covered the storage of Cox's Orange Pippin apples and English-grown William pears, and studies in the resistance of apples to fungal invasion have also been continued, as well as on the experimental storage of broccoli, the freezing of vegetables for preservation, the thermal properties of butter, and on the relation between the rate of formation of hydrogen swells in cans filled with various fruits and the rate of corrosion by acid of the steel base of the tin-plate used in their manufacture. The Advisory Council has now further invited the Board to review the whole field of research into the processing of foodstuffs and to submit proposals for embracing under its scientific supervision work in this field which is desirable in the national interest.

A further special aspect of food research is stressed in the report of the Advisory Council—that of preventing the loss of stored foodstuffs by attack. The destruction of grain by weevil and other pests is estimated to cause a loss in Great Britain of £500,000 annually, a figure which might easily be exceeded if the problem is left unsolved while the plans for storing grain in the national defence policy are developed. The Department has now accepted the responsibility for a survey of the infestation of grain and grain products in this country, covering all stages in the handling of the grain, from harvesting or arrival at the port to delivery to the consumer. A standing conference, representing all the industrial interests desiring to co-operate, has been established as a consultative

body, on which brewers, corn merchants, flour millers, railway companies, cattle food trades, wharfingers, maltsters, lightermen, farmers and port authorities are represented, and the work was commenced in May by the staff of the Stored Products Laboratory at the Imperial College of Science and Technology, London, under Prof. J. W. Munro.

Besides the work of the Food Investigation Board, several of the research associations have made important contributions to our knowledge of foodstuffs and dietary problems. The Research Association of British Flour Millers, for example, has been responsible for important investigations into the nutritive value of bread which have emphasized the importance of bread and lard, or bread and butter in the dietary, and other work has been concerned with developing the instrument for measuring and recording graphically the baking quality of flour and the conditioning of wheat prior to milling.

Investigations carried out by the Research Association for the Cocoa, Chocolate, Sugar Confectionery and Jam Trades, on the properties of different white sugars used for certain confectionery processes, have indicated that the differences in behaviour were due to differences in minute quantities of impurities in the sugars. This discovery has led to new operating methods and also substantial savings of sugar, and further investigations of the same type have shown that complaints by employees that certain brands of sugar were unsatisfactory for a specific purpose were justified. Other investigations of the Association have advanced our knowledge of the properties of pectin compounds and afforded a new explanation of the phenomena of jelly formation. The Food Manufacturers' Research Association has obtained important results in bacteriological investigations on the curing of bacon and hams, as well as on the canning of meat and on the corrosion and perforation of the cans and the methods of lacquering the cans to prevent corrosion.

LIGHT INDUSTRIES

Other research associations are making equally important contributions in the field of clothing. The Boot, Shoe and Allied Trades' Research Association, continuing its work on occupational footwear, has made good progress in research to discover the best styles of footwear for various kinds of employment, and other investigations commenced during the year deal with the influence of heel height upon poise. The results obtained in this intrusion on the thorny problem of the effect of high-heeled shoes on health suggested that the best height is governed by a woman's occupation

and the customary poise which her occupation may impose.

The Wool Industries Research Association has continued its investigation on shrinkage-resistant wool, including an entirely new type of reaction, which consists in the use of proteolytic enzymes of the type of papain whose activity can be controlled chemically and which appear to have specific action on certain regions of the wool fibre. Other work has been concerned with the rubberization process, the measurement of shrinkage in fabrics due to milling and laundering, and the fastness of dyed materials to washing. The Linen Industry Research Association has continued its work in relating yarn and fabric properties, and on degradation and fading of fabrics used for casements and awnings; it is now possible to select vat dyes which decrease the chances of premature deterioration. Similarly the British Launderers Research Association's investigations have thrown much light on the mechanics of the first part of the washing process, and its bacteriological investigations have shown that goods washed and finished in the laundry are much more nearly sterile than goods washed and dried in the home.

The British Leather Manufacturers' Research Association has continued its investigations on the chemical basis of the finishing process, and an X-ray plant has been installed for studying the effect of the various tanning processes on the internal structure of the fibres. The physical and microscopical characteristics of chrome calf and of glacé kid have been examined with the object of obtaining better quality leather for boot and shoe uppers. The Research Association of British Rubber Manufacturers has devised a method by which the ordinary dry raw rubber of commerce can be reduced to a fine granular condition by a simple process requiring no special machinery beyond that ordinarily used in rubber manufacture, while its investigations on ebonite have aimed at obtaining a material better suited to modern needs.

The Printing and Allied Trades Research Association has now passed a year in its new laboratories, and has completed an investigation into the causes of the tarnishing of bronze printing used in the decoration of goods for confectionery and cigarette wrappers, which has traced the tarnishing to minute quantities of compounds containing sulphur in the paper, ink or adhesives used. A method of determining these small quantities of sulphur has been devised which enables the materials to be tested as to their suitability. The Research Association of British Paint, Colour and Varnish Manufacturers has completed investigations on the surface characteristics of pigment particles and

their physical form in relation to their behaviour in paint, as well as on the role of oxygen in the formation of films by drying oils and varnishes.

HEAVY INDUSTRIES

It is impossible in the space at our disposal to refer to the work of all the research associations even, but three more examples can be given to illustrate how their activities contribute to almost every side of the amenities no less than of the necessities of society. The Electrical and Allied Industries Research Association has been giving attention to problems arising in making electricity supply more readily available to farms and in its more efficient application to agriculture and horticulture, as well as to the prevention of interference with broadcasting, the study of surge phenomena with the view of minimizing damage and inconvenience due to lightning, and the design of flame-proof mining switchgear. The British Non-Ferrous Metals Research Association has investigated the behaviour of copper pipes and galvanized tanks in the domestic water system, while the work of the Cast Iron Research Association has led to the development of cast iron with a tensile strength of more than sixty tons per square inch, although a few years ago a strength of more than about twelve tons per square inch could not be obtained.

FUEL

Investigations carried out by the Automobile Research Committee on the factors which affect the starting of automobile engines in the cold have shown that by an apparently minor modification in engine design the power of the engine to overcome its own internal friction can, under certain conditions, be doubled. Further investigations under this Committee have dealt with the tendency of piston rings to stick in their grooves, due to the formation of gum in the lubricating oil under the high-temperature conditions, and a comparatively simple test has been developed for measuring the gum-forming propensities of lubricants. Besides its chemical and physical survey of the national coal resources, the Fuel Research Board has dealt with the preparation of coal for the market and has continued its work on the hydrogenation of coal and tars to oils and motor-spirits and on the synthesis of hydrocarbons and the production of lubricating oils.

NATIONAL PHYSICAL LABORATORY

Turning now to the activities of the National Physical Laboratory, special stress is laid on the work carried out in regard to the testing of the electrical switch gear. The development of the

grid has entailed transmission of large amounts of power at high voltages and has called for much patient research into means for its control. An important problem is the provision of switchgear designed to ensure the safety of operators and to protect electrical equipment against accident. No public station is available for examining the behaviour of new designs and circuits reproducing serious conditions of overload which sometimes occur in service.

While the Department was considering the possibility of erecting such a station, a proposal for co-operation was made by the association of manufacturers owning the existing stations. It offered to open its stations to tests for any British manufacturer, with a guarantee that testing-time would be available at the stations as a whole equivalent to the full time of a Government station of the type contemplated. Moreover, it agreed to accept a measure of supervision of the tests by the Department which would make possible the issue of a National Physical Laboratory certificate for switchgear which passed agreed standards of performance. Such standards have already been drawn up by the British Standards Institution to cover circuit breakers of medium and high capacity. The negotiations necessary to accept this offer have been completed and the National Physical Laboratory is now prepared to accept orders for testing electrical switchgear designed to operate at voltages between 3,300 and 11,000 volts and up to capacities not exceeding 250,000 kva. for compliance with the provisions laid down in the appropriate British Standards specification.

Much important work has also been carried out at the Laboratory on the reduction of noise, including an investigation into the noise of motor-horns, while investigations are in progress for the Institution of Automobile Engineers on the silencing of motor-cycles and the reduction of drumming in motor-car panels, as well as on the lessening of noise in tube trains. Other work has been carried out in association with the Building Research Station on the transmission of sound through walls, floors and building materials, while in another department problems of illumination involving street lighting and the effect of illumination by the headlights of a motor-car under both dry and wet conditions have been investigated. An interesting side investigation has been that of the possibility of controlling the movement of eels in water by electrical fields, undertaken by the Laboratory at the request of the Ministry of Finance for Northern Ireland, instigated by the necessity of devising some alternative form of fishing owing to the obstruction to the discharge of water by an existing eel weir in a large drainage scheme on the lower

Bann River. In this investigation the possibility of diverting eels electrically on a small scale appears to have been established.

BUILDING AND ROAD RESEARCH

The Building Research Board, with its research station at Watford, has continued its work on the efficiency of buildings from the point of view of the user, and has been associated with the investigation on the strength of existing road bridges being undertaken for the Ministry of Transport.

The Road Research Board has continued its studies on the problem of skidding and on bituminous surfacings, in which the behaviour of the surfacings on a public highway is being compared directly with their behaviour on one of the road machines at the laboratory. It has also been associated with the Timber Development Association in investigations of the properties of wood block paving. A special investigation is being carried out for the British Rubber Producers Research Association on the effect of incorporating chlorinated rubber with tar.

MISCELLANEOUS

The Forest Products Research Board has been responsible for investigations ranging over the fire resistance of timber, the control of the death watch beetle or the lytus powder post beetle, glues and adhesives and the chemistry of wood. The Water Pollution Research Board has covered the base exchange process of water softening, the exchange properties of synthetic resins, the contamination of water by lead and the problems arising in the treatment and disposal of dairy waste water. Attention has also been given to the physical, chemical and biological changes which occur in the purification of domestic sewage by the active sludge process, while under the Chemical Research Board investigations have ranged over the preparation of new chemotherapeutic products; the evaluation of antiseptics, the tanning of tarred cordage, immersed corrosion and chemical reactions at high pressure. The cause of persistent contamination of beer by a sulphurous odour has also been investigated and the trouble removed. The variety of bacteria which are responsible for the trouble has been isolated, and the infection has been traced to the cellar floors of the brewery.

The Radio Research Board has completed its studies of the ionosphere and of the propagation of waves along the ground and through the atmosphere, which have become of direct practical importance with the increased use of ultra-short rays for communication purposes. Other work has dealt with problems of direction finding.

The Department has also been responsible for illumination research, including the daylight problems involved in illumination conditions in deep rooms and the standardization of lamps and fittings. Lubrication research carried out by the Department has included measurements of static friction, as well as work with the four-ball high-pressure testing apparatus and on the physical properties of surfaces. Atmospheric pollution, the detection of toxic gases in industry, the development of a respirator for use in dust-laden atmospheres, X-ray methods and measures conducive to greater

safety in handling gas cylinders and containers have all come within the orbit of the Department.

The present report gives a most impressive picture not only of the way in which the work of the Department of Scientific and Industrial Research serves almost every aspect of everyday life no less than the needs of industry, but also of the admirable way in which its organization is adapted for co-operative work on the many problems that are brought before it by industry or by national needs.

Marine Biology in South Africa

By Prof. R. S. Adamson and Prof. T. A. Stephenson,
University of Cape Town

SINCE 1932, an ecological survey of the South African coast has been in progress, carried out from the Departments of Botany and Zoology of the University of Cape Town. The survey is necessarily expensive, since it extends from Durban in the east to Port Nolloth in the west, covering a coastline between one and two thousand miles in length, parts of which are almost inaccessible. The expenses were defrayed, in the early stages, by the University of Cape Town and the South African Research Grant Board, with some private contributions; and assistance has also been received from the Royal Society of London. At the present time, expenses are being met from a generous grant made to the University by the Carnegie Corporation of New York.

The survey has been carried out by more than a dozen persons, but the principal contributions have been made by T. A. and Anne Stephenson, E. J. Eyre, G. F. Papenfuss and K. M. F. Bright. At present, thanks to the Carnegie grant, the survey employs three salaried research assistants and has been able to purchase a Chevrolet van for field-work.

The ecological results of the survey, up to the present, are being published in three periodicals. Accounts of specific areas on the coast have appeared during 1937-38 in the *Transactions of the Royal Society of South Africa* (24 and 25) and in the *Annals of the Natal Museum* (9). The first part of a general account of the results, as they affect the whole coast, is being published in the *Journal of the Linnean Society of London* (40). In addition to these papers by field-workers on the survey, systematic accounts have been published by specialists to whom collections, made in the course of the field-work, have been sent for identification. Altogether the survey has so far

been responsible for the appearance of thirty-two papers, references to which will be found in the publications just mentioned.

Material collected during the survey and belonging to certain animal groups is identified by specialists on the staffs of the South African and Natal Museums, and many of the algae are identified by Dr. Papenfuss, who is engaged upon a revision of the whole of the South African algae; but the greater part of the material has to be sent to specialists at various European or American centres, notably the British Museum. Throughout the survey, steady support has been received from this circle of systematic workers, invaluable assistance without which the continuation of the investigation would have been impossible. Sincere thanks are offered not only to these systematists, but also to those who have assisted the survey by publishing results, and particularly to Dr. R. F. Lawrence of the Natal Museum. Duplicates of all collected material are retained at the University of Cape Town for future reference.

The survey has hitherto been confined to a study of the rocky parts of the intertidal belt. The scope and aims of the investigation are detailed in the first paper¹ of the series mentioned above, but briefly it may be said to consist of three parts: (1) a general study of eight districts situated at intervals along the coast, from Port Nolloth in the west to Durban in the east; (2) a further study, at as many stations as possible, between the eight already mentioned; this section of the work to deal mainly with a selection of common organisms which have been shown by the eight primary surveys to be of particular importance; and (3) a series of experimental studies designed to explain the observed distribution in the field of ecologically important

organisms, in terms of their reactions to carefully controlled conditions in the laboratory; special attention being paid to temperature.

The reason why a survey of this nature is of particular interest in South Africa is found in the local arrangement of oceanic currents. The coast of Natal is markedly influenced by the southward-flowing warm Mozambique-Agulhas current, which renders the inshore water sub-tropical in temperature, although Durban is far south of the Tropic of Capricorn. The inshore water along the west coast of the Union, on the other hand, is almost sub-antarctic in temperature (particularly in its northern part), as the result of an upwelling of antarctic intermediate water. The tropical regions of the coast are therefore, as it were, displaced southward on the east coast and northward on the west. The south coast (Cape Point to Cape Padrone) is a region where the inshore water is of an intermediate average temperature, the influence of neither the coldest nor the warmest water of the other coasts being paramount. The situation is particularly interesting in the vicinity of the Cape Peninsula, on which Cape Town is situated, since here a narrow tongue of land, on the average about five miles wide, separates water-masses which, in summer, may differ from each other in temperature by as much as 8° C. The arrangement of currents is in fact more complex than this paragraph would suggest, but cannot be described in detail in an article of this nature.

The results of the initial phase of the survey show clearly that the South African intertidal belt has three principal populations of animals and algae, distributed in accordance with the arrange-

ment of currents described, and apparently controlled primarily by temperature. In Natal, the population consists partly of 'Cape' species, but a high percentage of the biota belongs to the great tropical Indo-West-Pacific group, and includes reef corals and many species which characteristically inhabit coral reefs. On the south coast (and indeed on the southern part of the east coast also), the bulk of the conspicuous tropical species has disappeared, and the population is a typical 'South African' one, with many endemic species. In the cold water of the west coast a third population holds the field. It should be understood that although these three series of organisms are undoubtedly distinct, if regarded as wholes, there is much overlapping, and although each group includes species which are confined to, and extend little beyond, their own optimal area, other species are common to two, or even all three, of the main geographical regions.

Although the survey has hitherto been primarily concerned with zoogeographical considerations, several specific side-lines have been followed up, and these include detailed studies of the bionomics of the South African Patellidæ¹, and of the intertidal snail-like gastropods², together with investigations of the oxygen conditions in rock-pools³ and of the recolonization of denuded intertidal areas⁴.

Epicentres of Earthquakes, 1913-1932*

By Ethel F. Bellamy, University Observatory, Oxford

THE Seismological Committee of the British Association has since 1911 made itself responsible, in a greater or less measure, for collating the records of earthquakes made by seismological stations all over the world. The work of computing the epicentres was first undertaken by Prof. John Milne at Shide, and on his death was taken over by Prof. H. H. Turner, who gave the *International Seismological Summary*† (formerly the *Bulletin of the B.A. Seismological Committee*) the form it now bears.

* Based on a communication at the Cambridge meeting of the British Association.

† Since the 1922 meeting of the International Union for Geodesy and Geophysics, the cost of preparation and publication has been met jointly by the International Seismological Association, the British Association, and the University Observatory, Oxford.

Such determination of epicentres, based on least squares solutions of the recorded times of arrival of *P* waves at the various stations, now covers both accurately and completely all the medium and large earthquakes recorded in the period 1913-1932 inclusive. It is the purpose of the present note to direct attention to the geographical distribution of these epicentres.

During this period, 7,940 shocks have been recorded, and these have originated in 2,865 separate and distinct epicentres. The positions of these epicentres are plotted in Fig. 1, an equal area projection centred on longitude zero, latitude zero. Attention may be directed to the density

Fig. 1.

POSITIONS OF 2,865 EPICENTRES AS DETERMINED IN THE INTERNATIONAL SEISMOLOGICAL SUMMARY, 1913-1932, INCLUSIVE. (Map reproduced by permission of Messrs. Stanford, Ltd.)

Fig. 2.

DISTRIBUTION OF 350 DEEP-FOCUS AND 30 SHALLOW-FOCUS EPICENTRES (1913-32).

On the original drawing the depth of focus is indicated by the nature of the circle, half-filled and filled, depending upon the depth, for deep foci, and with a central cross for shallow foci. Owing to difficulties of reproduction these distinctions will scarcely be discernible in the above figure.

(Map reproduced by permission of the American Museum of Natural History, New York.)

of epicentres in the Mediterranean zone, and along the east and west boundaries of the Pacific. Interesting, too, is the line of epicentres in mid-Atlantic, which follows so accurately the continental boundaries on either side, though whether this is due to a line of weakness or to a mere accident of distribution, the material available is still too small to settle.

Particularly interesting among these epicentres are those, to which Prof. Turner first directed attention¹, where the focus occurs at depths greater or less than normal. In the period concerned, there have been found 350 deep-focus and 30 shallow-focus epicentres; the positions of these are shown in Fig. 2, which is another equal area projection, centred on longitude 160° E. and latitude 20° N. It will be noted, as pointed out by Prof. Turner², on the basis of much less complete material, that the deep-focus epicentres appear to define the "boundary of an oval region about 180° long., centred with fair accuracy on

the Equator, and enclosing a considerable part of the Pacific Ocean, though its eastern boundary intrudes into S. America".

Maps such as these, which are a by-product of the work of preparation of the *Summary*, are not only of interest in themselves, but also serve to emphasize the need for a more uniform distribution of seismological stations. While approximately one third of the recorded earthquakes in the period under review occurred in the southern hemisphere, not one eighth of the existing five hundred seismological stations are located in that hemisphere. It is clear that such a one-sided distribution of stations cannot fail to affect the distribution of recorded epicentres, and it is greatly to be desired that new stations, with the accurate timing now made possible by the wireless broadcast of time signals, should be established in South America and South Africa.

Obituary Notices

Dr. L. H. Dudley Buxton

BY the death of Dr. L. H. Dudley Buxton, which took place at Oxford on March 5, at the early age of forty-nine years, the University of Oxford, Exeter College, and the study of anthropology alike suffer great loss.

Leonard Halford Dudley Buxton, the son of Dr. Dudley Wilmot Buxton, a well-known London medical man, was educated at Radley College, where he was senior scholar, and at Exeter College, Oxford, which he entered with an open classical scholarship in 1908. In addition to Honour Moderations and *Literae Humaniores*, he read for the diploma in anthropology, which he gained with distinction. Being more attracted by his scientific than his literary and philosophical studies, Buxton's interests turned to anthropology, and more especially, under the influence of the late Arthur Thomson, then professor of anatomy, to the study of physical anthropology. After a period of field work in the Sudan, he accepted a demonstratorship in physical anthropology in his University. Shortly afterwards the outbreak of War interrupted his work, and for four years he served in France in the Cameron Highlanders and in Intelligence—the latter a duty for which his facility in languages peculiarly fitted him. At the close of the War he returned to Oxford to carry on his work as demonstrator in the anatomical department of the University Museum, performing a highly useful service in arranging, classifying and cataloguing the osteological material, much of it, in some instances almost or quite forgotten, of no little value and interest in the annals of physical anthropology.

Not long after his return to Oxford, Buxton was awarded the Albert Kahn travelling fellowship, with which he travelled for a year in the United States, India and China, staying for some little time in the last-named country in order to travel inland. The opportunity thus afforded him of obtaining a first-hand acquaintance with a people still living in a condition of relatively primitive nomadism was one which his quick powers of perception could readily turn to account in its bearing on general theories of cultural development. How deeply he had been influenced by his contacts in China is apparent in the books, more especially the second, which he wrote on his return, "The Eastern Road" and "Primitive Labour", both published in 1924. In a further publication, "The Peoples of Asia" (1925), also, the quickness of his perception in marking racial character, and aptitude in ethnological analysis are readily to be noted.

This power of analysis was not confined to investigation of living peoples. Buxton had already excavated prehistoric osteological material on Cretan sites, and a visit to Mesopotamia, as well as the examination of the material which came from the excavations at Kish and elsewhere, led to an account of the basic types of the early peoples of the region, which is perhaps, in the technical sense, Buxton's best piece of work. No less valuable in a different context was the survey, anthropological in the broadest sense, which Buxton initiated of the peoples of the remoter districts of Oxfordshire, in which folk-lore, social history and custom, and anthropometric observation combined to produce studies of lasting interest.

In recognition of his discovery among family papers of the lost correspondence of Descartes with Huygens Buxton was awarded the *Légion d'Honneur*.

In due course, Buxton was elected to a fellowship on the foundation of his College, of which later he became bursar. The business ability which he showed revealed capacities of which the University also readily took advantage. In carrying out these duties, his success was at least in some measure due to a geniality which had won him the affection of his pupils, his colleagues and his contemporaries.

Mr. Howard Carter

It is with regret that we have to record the death, on March 2, of Mr. Howard Carter, the painter and archaeologist, whose name will always be remembered as the discoverer of the tomb of Tutankhamen.

Born at Swaffham in Norfolk in 1873, Carter was the youngest son of Samuel Carter, the animal painter. Owing to delicate health he never went to a public school but as a lad worked at painting with his father. At the age of eighteen years he first went to Egypt as a draughtsman on the staff of the Archaeological Survey of Egypt, then being carried out under the auspices of the Egypt Exploration Fund. His earliest line-drawings were published in the present writer's "El Bersah I" (1893), and many of his water-colour drawings of the animals and birds figured in the tombs at Beni Hasan, and executed in 1892, are reproduced in colour in "Beni Hasan IV" (1900). In 1892 he was for three months assistant to Mr. (now Sir) Flinders Petrie in the excavations that were then being carried out at El Amarna, Lord Amherst of Hackney defraying all Carter's expenses.

In the autumn of 1893 Carter was again in Egypt, this time as draughtsman to M. Naville at Deir el Bahari, and with Naville he worked for six years; the greater number of the plates of the six folio volumes of Naville's "Deir el Bahari" (1895-1903) were printed from Carter's drawings. In 1900 he was appointed inspector-general of the monuments of Upper Egypt under the Egyptian Government and during the four years that he held this post he did much restoration work in the temples of Western Thebes, Edfu, and Kom Ombo. In the Valley of the Tombs of the Kings he installed electric light in six of the more important tombs, and the electric light installation in the Temple at Abu Simbel in Nubia was also carried out by him.

In January 1902, at Carter's instigation, Theodore M. Davis, an American, undertook to finance a systematic exploration of the Valley of the Tombs of the Kings at Thebes for the benefit of the *Services des Antiquités*, and this work was entrusted to Carter. Among the discoveries he then made were the royal tombs of Tuthmosis IV (Carter-Newberry, "The Tomb of Thoutmôsis IV", 1904), and Hatshepsût (Neville-Carter, "The Tomb of Hatshepsûtu", 1906). When Lord Carnarvon began excavating at Thebes in 1908, Carter, at the express desire of Sir

Gaston Maspero, then director-general of the *Service des Antiquités*, was appointed to supervise the excavations and record all 'finds'. After five years work, there appeared the handsome volume "Five Years Explorations at Thebes" by Carnarvon, Carter and others. In 1914 Carter by a lucky chance found the long-sought-for tomb of Amenhotep I (*J. Egyptian Archaeology*, 3, 147; 1916), and soon afterwards he located a tomb of Princess Hatshepsût, which the Arabs had recently found and plundered (*ibid.*, 4, 107; 1917).

At the conclusion of the Great War, Carter persuaded Carnarvon to let him once again explore in the Valley of the Tombs of the Kings, and in 1922 he was rewarded by the discovery of the tomb of Tutankhamen with its extraordinary wealth of jewels and tomb furniture. Carter at once realized that only with the help of a large staff of expert workers could he attempt to clear the tomb of all the treasures it contained. Fortunately, this problem was quickly solved through the generosity of the Egyptian Expedition of the Metropolitan Museum of Art, New York. In answer to Carter's appeal, Mr. A. M. Lythgoe, the curator of the Egyptian Department of the Museum, placed at his disposal Mr. A. C. Mace, one of the associate curators, Mr. Harry Burton, their expert photographic recorder, and Messrs. Hall and Hauser, draughtsmen to their expedition. At the same time, Mr. Lucas, director of the Chemical Department of the Egyptian Government, offered his aid, and all were soon at work. During the years that followed other workers were enrolled, including Dr. Alexander Scott and Dr. Derry. Altogether it took ten years to record the contents of the tomb and to preserve the objects so that they might be safely packed for transport to the National Museum at Cairo. Carter and his staff published three popular volumes on the tomb and its contents between 1923 and 1933; but much remains still to be published and this it is hoped will soon be done by the Cairo Museum authorities. Only a few weeks ago Prof. Georg Steindorff published, in the *Annales des Services des Antiquités de l'Égypte*, 38, 641-667, a full account of the paintings on the walls of the tomb.

PERCY E. NEWBERRY.

Mr. E. R. Bolton

EDWARD RICHARDS BOLTON, who died on February 10, was born in Dublin in 1878, and was the only son of J. A. Bolton of Blackrock, Co. Dublin, of long Irish ancestry. He was at school at Bedford (Elstow) and studied chemistry at King's College, London, and in Fresenius's laboratory, Wiesbaden. On his return to England he was engaged for a short period in heavy chemical industry in Newcastle and in 1902 became chemist to the East India Products Oil Mills, Hammersmith, later Loders and Nucoline, Ltd. At these mills, Bolton carried out the first caustic refining of coco-nut oil in Great Britain. He became a director of the firm, having in the meantime started in analytical and consulting practice in Hammersmith.

Bolton quickly established a commanding position as analyst, consultant and technical adviser in the oil and fat and many food industries. In 1920, Technical Research Works Ltd. was founded, with premises in Milner Street, Sloane Square, Bolton being managing director, and transferring his analytical and consulting practice to the same address. 1920 is notable, too, in that it is the date of Bolton's patent for the continuous hydrogenation of unsaturated oils, fats and the like.

Much original work came from Bolton's fertile mind and clever hands: it was published mostly in the *Analyst*, from the year 1910, his last two papers (with K. A. Williams) being in 1938, both dealing with whale oil: his aptitude in devising apparatus and instruments is exemplified in the Bolton and Williams colorimeter. He also served on a number of research committees, particularly on analytical methods; at the time of his death he had just begun work with the "S.P.A." Sub-Committee on the determination of unpolymerisable matter in oils. Outstanding among his publications, there appeared in 1911 his book "Fatty Foods" (Bolton and Revis) a second edition of which, with the title "Oils, Fats and Fatty Foods" (Bolton) came in 1928.

Bolton was a well-known member of many societies; particular mention should be made of his services to the Society of Public Analysts and Other Analytical Chemists, of which he was honorary secretary from 1915 until 1925 and president during 1926-1927. For a period he was honorary treasurer of the Federal Council for Chemistry, and later was a member of the British Council for Chemistry of the Royal Society, a member of the delegacy of King's College, London, and a Royal Institution Visitor.

Seemingly in the full vigour of life, Bolton died, suddenly, after an illness from which he was thought to be recovering, leaving a widow and a host of friends to lament his loss. He was a remarkable and much-loved man, held in universal regard and affection alike by his staff, his colleagues and a wide circle of professional and business friends. His death is a serious loss to the profession of chemistry; yet throughout his life he did much to minimize this loss, for generosity in giving to others the fruits of his own gifted mind and of his wide experience was a notable characteristic of his ever-generous nature.

E. HINKS.

Prof. C. C. Okell

PROF. CHARLES CYRIL OKELL, who died on February 9, was educated at Douglas Grammar School, St. John's College, Cambridge, and St. Bartholomew's Hospital, and distinguished himself as a student. He became medically qualified during the Great War and served in the R.A.M.C. as lieutenant and captain in France, Palestine and Egypt, and was awarded the Military Cross when a regimental medical officer. Soon after the War he became bacteriologist to the Wellcome Physiological Research Laboratories at Beckenham, and left that institution to become professor of bacteriology at

University College Hospital Medical School, London. He was for some time assistant editor of the *Journal of Pathology and Bacteriology* and at the time of his death was editor of the *Journal of Hygiene*.

Okell's active scientific life began at Beckenham. He was soon engaged in what has since become one of the main labours of the laboratory—the investigation of the problem of human immunization against diphtheria. He collaborated with Glenny in an important paper on the meaning of the Ramor flocculation test for diphtheria antitoxin. This was followed by a large volume of work on the problem of immunization against scarlet fever and a number of papers on the hæmolytic streptococcus and its toxin. He was also concerned in a comprehensive examination of the sugar reactions of the diphtheria bacillus and the development of an intracutaneous test for the virulence of diphtheria bacilli which made the routine testing of virulence much cheaper and more practical. He also published papers on the standardization of dysentery antitoxin, scarlet fever antitoxin and tuberculin, and was among the first to realize the importance of the application of statistical methods to biological assay.

Okell was part author of a paper which was perhaps the first to establish with statistical rigour the fact that 'B.C.G.' had some immunizing power against virulent tubercle bacilli. One of his last efforts at Beckenham was his attempt with Hindle to establish the possibility of vaccination against yellow fever, an exciting and dangerous piece of work, which he approached in the same spirit of detachment which characterized all his efforts.

On his appointment to the chair at University College Hospital Medical School, Okell delivered the Milroy Lectures in 1932, in which he summarized the fruit of his labours for many years on the hæmolytic streptococcus. He also made the discovery that simple operations such as tooth extractions are followed in a large number of cases by the appearance of streptococci in the blood of the patients, a most important observation which he would have followed up but for the rapid onset of the ailment which led to his retirement to Cambridge.

All Okell's work was done in collaboration with others. He loved the company of his fellows both in work and in leisure. He did not like working alone, and always discussed what he was doing with all and sundry. He was a great conversationalist, and was always worth listening to, not only when talking of his special subject, but also when ranging at large over literature, art and ethics. In none of the work in which he collaborated was his contribution the least important factor and he was generally the moving spirit. His work was never far removed from practical application. Interested though he was in fundamental problems, it could be seen that the motive of his work was primarily the benefit of the sick, particularly in the prevention of disease.

Okell was universally popular, and the gradual restriction of the field of his labours by his illness was a grief to all of his friends. He leaves a memory of care for others and single-hearted devotion to medicine which will endure.

J. W. TREVAN.

News and Views

New Fellows of the Royal Society

At the meeting of the Royal Society, held on March 16, the following were elected fellows of the Society:

G. S. ADAIR, assistant director of research in physiology, Cambridge, distinguished for his researches on the physical chemistry of proteins, particularly in connexion with haemoglobin.

C. H. ANDREWS, pathologist, National Institute for Medical Research, distinguished for his work on filtrable viruses and the bacteriophage, particularly in relation to the neutralization of viruses by antisera, and his studies on filtrable tumours.

M. BORN, Tait professor of natural philosophy, University of Edinburgh, distinguished for his work in many branches of mathematical physics, and particularly for his contributions to quantum theory and its applications to physics and chemical physics.

A. J. BRADLEY, assistant director of research in crystallography, Cavendish Laboratory, Cambridge, distinguished for his methods of applying X-ray crystallography to elucidate the structure of metals, and particularly the gamma phase and order and disorder in alloys.

D. BRUNT, professor of meteorology, Imperial College, London, distinguished for his contributions to analytical and dynamical meteorology, and particularly to the theory of the transfer of heat in the atmosphere.

F. A. E. CREW, Buchanan professor of animal genetics, University of Edinburgh, distinguished for his work on sex reversal in frogs and birds and on the genetics of many animals, especially *Drosophila* and budgerigars.

F. W. EDWARDS, Department of Entomology, British Museum, distinguished for his extensive researches on the order Diptera and for his studies on larval characters in relation to classification.

B. M. JONES, Mond professor of aeronautical engineering, Cambridge, distinguished for his researches in aeronautical science and for the elucidation of problems of design, such as the control at slow speeds and the determination of drag on full-scale structures.

G. W. C. KAYE, superintendent, Physics Department, National Physical Laboratory, distinguished for his pioneer work in X-ray measurements and for his studies on acoustics and physical constants: has rendered valuable service to the Radium Protection Committee and the National Radium Commission.

E. G. T. LIDDELL, fellow of Trinity College, Oxford, distinguished for his researches upon the physiology of muscle movement and posture in mammals, and upon their control during the normal and abnormal functioning of central nervous mechanisms.

E. J. MASKELL, lecturer in plant physiology, Cambridge, distinguished for his work in the realm of plant physiology, especially in relation to problems of translocation.

I. MARSON, vice-chancellor of the University of Sheffield, formerly professor of chemistry, University of Durham, distinguished for his researches in physical chemistry, particularly on the physical interaction of mixed gases and on new aspects of the chemistry of iodine.

O. E. K. MEES, vice-president of the Eastman Kodak Company, Rochester, N.Y., distinguished for his influence on the technology of photography, thereby assisting advance in many branches of science.

M. H. A. NEWMAN, lecturer in mathematics, Cambridge, distinguished for his contributions to pure mathematics, particularly in the field of topology and group theory.

H. H. READ, professor of geology, Imperial College, London, distinguished for original work especially in connexion with the tectonic and petrological problems of the igneous and metamorphic rocks of northern Scotland.

SIR R. G. STAPLEDON, professor of agricultural botany and director of the Welsh Plant Breeding Station, Aberystwyth, distinguished as the founder of the Welsh Plant Breeding Station where, with a team of workers, he has undertaken studies of far-reaching importance on the improvement of pastures.

H. M. TURNBULL, professor of morbid anatomy and director of the Bernhard Baron Institute of Pathology, London Hospital, distinguished for his work on morbid histology, particularly in relation to vascular disease, encephalitis, toxic hepatitis, diseases of bone, and normal and abnormal haemopoiesis.

E. E. TURNER, head of the Department of Organic Chemistry, Bedford College, London, distinguished for his contributions to the stereochemistry of organic compounds, especially in connexion with asymmetry in derivatives of diphenyl and with dissymmetry in the phenoxarsines.

V. B. WIGGLESWORTH, reader in medical entomology, London School of Hygiene and Tropical Medicine, distinguished for his researches on insect physiology, especially in relation to digestion, tracheal respiration, excretion and possible endocrine secretion.

E. J. WILLIAMS, professor of physics, University of Wales, Aberystwyth, distinguished for his researches on the passage of electric particles through matter, and on individual collision processes, which have provided evidence for the existence of the heavy electron.

Dr. C. H. O'Donoghue

DR. C. H. O'DONOGHUE has been appointed to the chair of zoology in the University of Reading in succession to Prof. F. J. Cole (see *NATURE* of March 4, p. 368). After graduating with first-class honours in zoology and physiology from King's College, London, he was appointed lecturer in zoology at University College. He obtained the D.Sc. degree in 1912, was awarded a Beit Memorial Scholarship for research and spent six months studying at Freiburg under Prof. F. Doflein. In 1918 he went to Canada as professor of zoology in the University of Manitoba, and in 1923 acted as director of the Marine Biological Station at Nanaimo, Vancouver Island. For two terms he was visiting professor at Stanford University, California. He was also appointed by the Canadian Government for two years as head of a scientific expedition to Jasper Park in the Rocky Mountains. As a member of the Research Committee of the Biological Board of Canada, he helped to establish the Prince Rupert and Cultus Lake Stations. In 1927 he returned to Great Britain at the invitation of the late Prof. J. H. Ashworth, to become senior lecturer and later reader in zoology in the University of Edinburgh. In 1932 he was awarded the Neill Prize of the Royal Society of Edinburgh, and he was president of the Royal Physical Society of Edinburgh in 1933. His research covers a wide field, but is chiefly concerned with the taxonomy of the Bryozoa and Nudibranchia, and with vertebrate anatomy, physiology and embryology.

Prof. M. Leclerc du Sablon

CONGRATULATIONS are to be extended to Prof. Mathieu Leclerc du Sablon, who attains his eightieth birthday on March 25. Prof. Leclerc du Sablon is probably the last living member of the famous group of French botanists who at the end of the nineteenth century made very important contributions to the study of plant anatomy. From 1883 until 1890 he was working in Paris at the École Normale Supérieure, and later at the Natural History Museum under Van Tieghem, his father-in-law and teacher. During this period he produced a series of important papers on various subjects in some of which are facts now taught to every student of elementary botany. His studies on the dehiscence mechanisms of anthers in the flowering plants and of the sporangia in the Archegoniatae are especially noteworthy; he was the first to discover the mechanism of the annulus in the fern sporangium. Other important contributions were papers on the structure and physiology of tendrils, on the haustoria of parasitic flowering plants, on the development and comparative structure of the sporophytes of Liverworts, and on the development of the vascular system in young fern plants. In 1890 he was appointed professor of botany in the University of Toulouse, a post which he held for thirty years. His extensive knowledge of plants found expression in the "Cours de Botanique", a large text-book written in collaboration with Gaston Bonnier, his brother-in-law and former colleague. The first part of this work appeared in 1901; but it

was not completed until 1938 when, after the death of Bonnier, the last part dealing with plant physiology was published. His activities have covered an exceptionally wide field, and his influence on the development of botany, especially in France, has been very considerable.

Archaeological Studies in France

PROF. H. V. VALLOIS, professor in the Faculty of Medicine of the University of Toulouse, has been appointed professor of prehistoric anthropology in the Institut de Paléontologie humaine of the University of Paris. Prof. Vallois, who has long been recognized as standing in the front rank of authorities in France on human palaeontology, has been in charge of the anthropological laboratory for practical studies of the École des Hautes Études in Paris since 1937, and is senior editor of the periodical *L'Anthropologie*. He took up his duties at the Institut at the beginning of the current semester, and is delivering a course of lectures on the general principles of human palaeontology and the prehumanids. A course of lectures on prehistoric ethnography is also being delivered concurrently by the Abbé Breuil. A new department has been formed in the École des Hautes Études for the study of geology with special reference to the origin of man. The first director of the department will be P. Teilhard de Chardin, who during his prolonged residence in the Far East has made numerous and important contributions to the study of the palaeontology and pre-history of China and south-eastern Asia. It will be remembered that the first discovery of palaeolithic implements in China was due to Teilhard de Chardin, while his studies of the fossil fauna of Choukoutien is the basis for the dating of Peking man. He contributes to the current issue of *L'Anthropologie* (48, 5-6; 1938) notes on the human palaeontology of southern Asia, summarizing the results of his observations in Burma, Malaya, Java and Indo-China, when accompanying Dr. Hellmut de Terra on his recent geological and archaeological survey in the Far East, supplementary to his investigations in India (see *NATURE*, 143, 275; 1938).

German Activities in Central Europe

DURING the past fortnight, the State of Czechoslovakia has been forcibly broken up and a large part absorbed into the "Great German Reich" as the "Protectorate of Bohemia and Moravia". In the account of Czechoslovakia's contributions to science which appeared in *NATURE* of November 26, 1938, pp. 942-44, the hope was expressed that the scientific and cultural development of the Czechs would still be possible after their territory had been drastically curtailed by the Munich Agreement, and that they would continue to make contributions to the advancement of scientific knowledge and take a share in its application to the welfare of mankind. This hope was qualified by the anxiety then felt for those men of science and learning whom the impoverished State might not be able to support, and it is gratifying to know that, until recently, indeed

until the very end, the educational authorities succeeded in maintaining practically all the important research institutions and cultural associations remaining within the country. Scientific publications also continued to appear, and there was every reason to believe that the nation would, by hard labour, maintain its vigour and prosperity, and its men of science would be able to continue to achieve distinction and add to the sum of human knowledge by meritorious work in their respective fields. It is, perhaps, too early to foresee the consequences of the latest events in Central Europe. The new Protectorate is avowedly to have a measure of autonomy, though this is scarcely likely to go so far as to permit the free and open interchange of thought which has been banned in Germany for the past few years.

Tuberculosis in Wales

THE report is published of a Committee, consisting of Mr. Clement Davies and Dr. F. J. H. Coutts, appointed by Sir Kingsley Wood, when Minister of Health, in response to a request of the King Edward VII Welsh National Memorial Association for an inquiry into the anti-tuberculosis service in Wales and Monmouthshire (London: H.M. Stationery Office. 4s. 6d. net). The problem of tuberculosis is relatively more serious in Wales than in England, for the mortality rate has not declined so rapidly as, and exceeds, that of England. Excessive mortality in Wales occurs among young adults aged fifteen to twenty-five years and in the age group twenty-five to forty-five. In contrast with England, the rates at fifteen to twenty-five show little change since 1921 and the rate for females is distressingly high. Certain areas, notably Anglesey, Caernarvon and Merioneth, are especially afflicted with the disease. The report states, that for practical purposes, racial susceptibility as a factor in causing the high mortality may be ignored. Segregation in tuberculosis is one of the most effectual preventive measures against the spread of the disease, the need for additional bed accommodation if tuberculosis is to be adequately dealt with is stressed, and it is suggested that, with a widely scattered population in some Welsh areas, small local institutions of a simpler type might be a valuable adjunct to the more fully equipped hospitals. The Committee recommends the provision of additional laboratory accommodation, and suggest that the proposal to establish a village settlement in Wales should be explored.

It is pointed out that after-care work has made little headway in Wales, and although the Committee does not recommend that the Association should undertake this work, the hope is expressed that local authorities will realize the importance of setting up effective care organizations. Treatment is only one aspect of tuberculosis work, and the importance of preventive work should be realized. Unfortunately, over large areas in Wales, preventive duties are neglected or are carried out imperfectly by local

authorities, who do not appear fully to realize their responsibilities. In regard to housing, the report states that in rural areas, villages and small towns there are hundreds of houses that are unfit for habitation. The Committee also points out that there is scope for much improvement in the provision of milk and meals in schools, and authorities in Wales as a whole, with few exceptions, make little or no provision for midday meals. The Committee concludes by directing attention to the great disparity among local authorities in the standard of performance of public health services, and remarks that many of the authorities, owing to small population and inadequate resources of their area, are incapable of carrying out their public health duties properly. The Committee was impressed with the general efficiency of the Welsh National Memorial Association's work for the treatment of tuberculosis.

Launch of the R.R.S. *Research*

THE launching of the Admiralty non-magnetic ship, the R.R.S. *Research*, will take place at 6 p.m. on April 4 at the Noes Works, Dartmouth, of the builders Messrs. Philip and Son, Limited. The launching ceremony will be performed by Mrs. Spencer Jones, wife of the Astronomer Royal. The day and time of the launching have been chosen to coincide with the highest spring tides, as investigations proved that the *Research*, which is a 770-ton ship, would need all the water possible. The construction of a special vessel such as this, which is to be so far as possible non-magnetic, raises many problems. The question of the best substitutes for iron or steel in various components and fittings has required a good deal of investigation and experiment. The builders have shown a great interest in the work and have co-operated with the Admiralty to obtain the most satisfactory results. Lieut.-Commander D. H. Fryer, who has been appointed captain of the *Research*, was given special leave by the Admiralty to make a voyage to Australia in one of the grain ships in order to gain experience of sailing ships. He has recently completed the rigging of a scale water-line model of the *Research*, which will be on view at the reception to be given by Messrs. Philip and Son after the launching.

Recent Researches in Steel Metallurgy

IN a Friday evening discourse at the Royal Institution on March 17, Dr. W. H. Hatfield discussed what he described as the three principal aspects of steel research: (a) elucidation and improvement of the process of steel manufacture and manipulation; (b) the investigation of the properties of steel under variable conditions approximating to those of service; and (c) the exploration of the influence of added elements and of the effect of heat-treatment. Dr. Hatfield showed a colour film illustrating the electric and open-hearth steel processes, the casting of ingots and forging operations. Dr. Hatfield said that one of the most complex studies is that of the changing properties of steels with varying temperature, this

study not only including the properties of the steel at a particular temperature but also the degree of persistence of these properties at that temperature over long periods of time. In this connexion, details were given of a creep test carried out on a heat-resisting steel maintained under a load of 280 lb. per sq. inch for a period of 10,000 hours at 900° C. With reference to the production of permanent strain at normal temperatures, Dr. Hatfield instanced a test now in progress at the Brown-Firth Research Laboratories. The experiment consists of a strip of cold-worked austenitic steel placed in tension under a stress of 25 tons per square inch. The test was commenced in June 1929, and since that date the extension has been nil within the accuracy of measurement applied, that is, a sensitivity of 1/40,000 of an inch and a gauge length of 8 inches. In discussing the results achieved by the addition of alloying elements, Dr. Hatfield stated that, experimenting upon the basis of the rustless steel composition by modifying the chromium and nickel, and by adding other elements such as tungsten, molybdenum, cobalt or titanium, steels have been produced which maintain a reasonably protective film at temperatures even in excess of 1000° C., besides possessing a useful strength.

Palaeolithic Man in Northern England

ALTHOUGH it is more than sixty years since the late Sir William Boyd Dawkins brought to light evidence of the presence of man during the Upper Palaeolithic period in the north Midland region of England, it was not until Mr. A. Lealie Armstrong's investigations in the cave and other deposits of the area in a series of systematic researches, which began in 1921, that it became possible to establish a chronological succession in human occupation here in the course of the palaeolithic age, and its relation to phases of the Ice Age. The results of these investigations were surveyed by Mr. Armstrong in his Wildé Lecture before the Manchester Literary and Philosophical Society on March 14. In dealing with the earlier evidence of occupation, he pointed out that until three years ago it had not been known that the range of Lower Palaeolithic man extended to the northern Midlands, but intensive research directed to the contents of the glacial drift and old river terrace gravels of the Trent and its tributaries had provided evidence of his presence there in the form of hand-axes of flint and other artefacts, representing all the Lower Palaeolithic cultures. Excavations in the Pin Hole Cave, Creswell, revealed three zones of occupation in Mousterian times, including two cold periods. Mr. Armstrong's Trent Valley researches indicate that the lower terrace gravels of the river approximate in time to the second Mousterian occupation of the cave, and that they were laid down during one, or possibly both, of the cold periods recorded in the cave. Rock shelters in the Creswell gorge and neighbouring valleys and habitation sites on the Lincolnshire cliff, covered by solifluxion deposits, indicate that man lived in these regions while events which mark the final glaciation

of England were active in the east, west and north of the region; therefore human occupation of the north Midland area throughout palaeolithic times can now be demonstrated.

Archaeological Finds in the Nile Delta

AN archaeological discovery described as "exceptionally important" is reported from the ancient city of Tanis in the Sharkia Province of the Nile Delta (*The Times*, March 20). Prof. Montet of Strasbourg, who has been engaged for some years in excavating on the site, on which both Mariette Pasha and Sir Flinders Petrie carried out archaeological investigations, has discovered the first gold coffin to be found in Egypt since that of Tutankhamen, and a silver sarcophagus, the first example in that metal from Egypt. Tanis was the capital of Egypt between the Thirteenth and Eighteenth Dynasties; but the present find was made in excavating a series of funerary chambers of the tombs of kings of the Twenty-first and Twenty-second Dynasties (1100-950 B.C.), the capital of which was Tell Basta, the site of the modern Zagazig. Hitherto there has been no certain knowledge of the residence of these kings. The funerary chambers were empty, but a few days ago a narrow corridor was found leading to a wall which, when pierced, gave entry to an intact chamber of medium size, built of white limestone, and containing a gold sarcophagus. Within this sarcophagus was a second of silver, in which was a mummy. Inscriptions show that it is that of King Shishak. Two human skeletons still wearing ornaments were found on either side of the sarcophagus; and there were many jewels among the remains. In one corner of the tomb were funerary statuettes representing King Cumin, and in another corner a large vase, which has yet to be opened.

Libraries in Technical Institutions

A REPORT on libraries in technical institutions, which has been issued by a joint committee of the Association of Technical Institutions, the Association of Principals of Technical Institutions and the Association of Teachers in Technical Institutions, should be of considerable service to those responsible for providing and maintaining library services in technical colleges (Loughborough: Loughborough College, 1939). In addition to a clear analysis of the aims of such a library service, which should assist in the formulation of sound policy based on well-defined principles, it gives sufficient detail in regard to such matters as accommodation and planning to be of real service in the design of a new library or expansion of existing services. A feature of the report is the inclusion of plans and details not only of three distinct types of library design but also of a number of representative libraries. The basic recommendation of the report is that in every technical institution there should be at least one room of adequate size reserved solely as a library, containing an ample supply of books and periodicals kept thoroughly up to date and covering all departments of work carried out in the institution, and including also a good

collection of books of general interest. Wherever possible there should be a separate reading room, and in institutions doing advanced work small rooms should be provided for individual study and research. To secure full value from the library service, the library should be under the supervision of someone who has had a measure of special training and experience in library work. Alternative methods of recruitment to this end are discussed in the report. It is further recommended that properly qualified librarians employed in technical institutions should always be regarded as equal in status to members of the teaching staff and be paid on the Burnham Technical Scale—graduate or non-graduate—according to qualifications. An annual allocation for the provision of books, periodicals and binding of 3s. per student for the first 2,000 students and 2s. per student for each subsequent student is recommended.

Uniformity of Mycological Terms

THE Plant Pathology Committee of the British Mycological Society has addressed a circular letter to organizations in the British Isles which use the scientific names of fungi causing plant diseases. It is suggested that an agreement to use the names from a standard list of plant pathogens would be of great convenience, and would strengthen attempts to secure international uniformity. The proposed standard names are those included in the "List of Common Names of British Plant Diseases" (published for the Plant Pathology Committee of the British Mycological Society by the Cambridge University Press, 1934). Mycological nomenclature is greatly in need of any authoritative lead such as the one now proposed. It would, in fact, be very gratifying if the present modest suggestions should not only find immediate acceptance, but would also be extended later. A universally acceptable standard of naming for all fungi is urgently needed. The British Mycological Society has, moreover, always maintained a proper balance between all the branches of its study. It should, therefore, be accorded the full support of all mycologists of Great Britain. The Society has accepted its Committee's suggestions on nomenclature for all papers on pathogenic fungi, which will be published in its volumes of *Transactions*. Provision has been made for any desirable criticisms to be advanced against the actual list of names, and it is proposed to issue periodical revisions. Further particulars of the scheme may be obtained from the Secretary of the Plant Pathology Committee, Dr. G. C. Ainsworth, Experimental and Research Station, Cheshunt, Herts.

Horticulture of the Amaryllidaceæ

"HERBERTIA", the fifth year-book of the American Amaryllis Society (From the Editor, Mira Flores, Orlando, Florida, U.S.A., 1938) maintains a proper balance between needs of the grower, the scientific worker and the teacher, and attains a human interest in addition. The present volume is dedicated to Ernst H. Krelage (Holland), about whom an

interesting autobiography appears. Classification of the Amaryllidaceæ is somewhat difficult, but a series of papers by Dr. H. P. Traub and J. C. Th. Uphof clarifies some obscurities and makes possible a tentative revision of the genus *Amaryllis*. Cytological studies have also been used by Walter S. Flory to re-establish the genus *Habranthus*. Experiments by W. M. James upon vernalizing seed of *Leuocoryne Ixioides* indicate the possibility of much faster production of flowering-size plants. I. W. Heaton reviews the possibilities of growing hybrid amaryllids with culture solutions instead of compost, and preliminary experiments suggest a useful and extremely economic method of culture. The section on harvesting, storage and forcing contains two mutually complementary papers by Dr. John Grainger (England), who describes the scientific principles underlying the production of early bloom, and by Prof. E. van Slogteren (Holland), who considers the practices for early forcing. "Herbertia" has also the usual descriptions of regional activities and garden culture. It is comprehensive, and succinct yet adequate. The policy of Dr. Hamilton P. Traub, its editor, presents the requisite blend of new and established knowledge which is essential for progress in modern horticulture.

A Doctors' Peace Manifesto

THE Balkan Medical Union (Athens, Belgrade, Bucarest and Istanbul) has addressed an appeal to medical men of all nations to take active measures to awaken public opinion on the horrors of war, and the terrible sufferings it inflicts upon the civil population of open towns. The Union believes that "only enlightened international opinion can make plain the imminence of the danger, and the uselessness, even for the victor, of war-time atrocities. The immutable truth that hate breeds only hate, and atrocity breeds vengeance, must be impressed on everyone". The Balkan Medical Union, founded in 1931, is essentially a scientific organization; but it also aims at bringing together the intellectuals of different countries so that they may know one another, and come to a mutual respect and understanding, whereby the misunderstandings that engender hate and disastrous struggles between nations may be dispelled.

The League of Nations

A REVISED edition of the "Aims, Methods and Activities of the League of Nations", which first appeared in 1935, has now been published (Geneva: League of Nations; London: George Allen and Unwin, Ltd., 1938. 2s.). Like the first edition it consists of four parts, the first including a historical account of international organization followed by a description of the nature, aims and methods of the League. The second part attempts to describe and assess impartially the achievements of the League, and although eminently readable and not overburdened with detail, gives a good comprehensive account of its work, which at the same time indicates some of the causes of its success and failure. The chief criticism that can be advanced of this section,

which occupies the greater part of the book, is that in attempting to be comprehensive it fails to evaluate sufficiently—the highly significant work of the League in the field of nutrition, for example, receives the barest mention. The work of the Permanent Court of International Justice and of the International Labour Organisation are dealt with in the third part; the final section of the book containing the text of the Covenant and extracts from the Statute of the Permanent Court and from the Constitution of the International Labour Organisation.

Hospitals in War Time

THE Minister of Health has issued to all hospital authorities and voluntary hospitals a memorandum explaining the main lines on which a scheme for a war-time hospital organization is being worked out for England and Wales (Emergency Medical Services Memorandum 2. H.M. Stationery Office. 6d. net). The basis of the emergency scheme is the division of hospitals into different classes according to the use which it is intended that they should serve, and almost all hospitals are included in some way. Room is to be made for the reception of casualties in one wing or block of most of the mental hospitals in the country, and a few mental hospitals are to be cleared of their ordinary patients. It is proposed to link up casualty hospitals to each other in the more vulnerable areas and to selected hospitals farther away. In order to increase the hospital accommodation, all hospitals would be asked to discharge all patients for whom institutional treatment is not essential, which it is estimated would probably free from 30 to 50 per cent of the existing hospital beds, and additional beds would be introduced into selected hospitals and institutions. Proposals for the organization of the medical and nursing staffs are also outlined.

Physical and Mental Welfare

THE Physical and Mental Welfare Society of New Zealand, Onehunga, N.Z., suggests that the centenary of New Zealand might be celebrated by the foundation of a memorial, and that this might take the form of an endowed scheme whereby the 'masses' might be kept in touch with scientific truths and views bearing upon the physical and mental welfare of the race. New Zealand was recognized as an independent Colony in 1841. Bearing on this subject, the Health Organisation of the League of Nations has issued reports on physical education and on nutrition (*Bull. Health Organisation*, 7, No. 4, 1938. Allen and Unwin, Museum Street, W.C.1. 2s. 6d.). The first report suggests a programme of laboratory research upon the effects of physical exercise, and on the relation between intellectual and physical development. The other report deals with principles to be observed in the study of diets and of the nutrition of a population, particularly as regards nutrition in the tropics.

Disposal of Offal

IN the Benjamin Ward Richardson Lecture recently delivered at the Royal Sanitary Institute, Mr. John Austin dealt with the hygienic treatment

and disposal of offal and by-products in abattoirs. He said that two most important considerations govern the treatment of animal offal, namely, (1) the hygienic disposal of animal waste matter, and (2) its economic utilization. Suitable premises are needed to which all raw material can be brought from the slaughter-hall with the minimum amount of handling; they should be well lighted and ventilated and provided with an abundant supply of steam and hot and cold water. Mr. Austin then considered by-product work under the headings of blood, hides and skins, tripe, casings, edible fat and inedible offal, all of which require immediate treatment owing to the rapidity of decomposition after slaughter.

British Chemical Industry

A SURVEY of the achievements of British chemical industry in the last twenty-five years was given by Sir Gilbert T. Morgan in three Cantor Lectures to the Royal Society of Arts which have just been published. The field covered included inorganic chemicals, gases, nitrogen products, pigments, electro-chemistry, metals, the utilization of coal, explosives, dyes, fermentation, plastics and drugs, and the lectures give a valuable survey of modern processes and the progress made in the period considered.

Centro Volpi Di Elettrologia

THE second number of this journal (English edition) mentions that amongst the first of its activities will be a convention for the development of 'experimentations' in view of industrial autarchy. In order to develop research work, which is the basis of industrial emancipation, Italian industrialists and the 'most competent scientific workers and technicians of the country will meet in Venice during October 26-28. They will examine the many sides of the problem of the improvement of existing laboratories, the creation of new ones and the co-operative work between them. The centre extends its welcome to all those who wish to attend the conventions. In the field of international relations the Centre is endeavouring to establish collaboration.

Safeguarding of Unpublished Research

SUCH attempts as were made by individuals or institutions to remove important papers to places of greater safety during the September crisis merely served to emphasize the impossibility of handling at short notice the quantity of material involved. The Research Co-ordination Committee accordingly decided to continue its investigation of the possibilities of micro-film technique. In view of recent international developments, the steps taken by the Research Co-ordination Committee to facilitate the reproduction and storage of documents are particularly timely. The process was described in *NATURE* of March 11, p. 393. Briefly, it consists in photographing documents of any kind, such as charts, pages of books, loose sheets, maps, etc., on to standard 35 mm. cine-film. Documents up to 17 in. x 24 in. can be dealt with (or larger ones in two or

more sections). The photographs are preserved in negative form on acetate safety film, which when tightly rolled is far more resistant to fire than any paper record. Working with quarto papers (10 in. $\times$ 8 in.), 1600 facsimiles can be obtained on 100 ft. of film. This micro-record occupies only one twentieth of the volume of the original. Full-size prints can be made from it at any time, or it can be read in a special projector, or thrown on a wall-screen for lectures. Preliminary arrangements are in hand for making micro-film records at the cost of one half-penny per quarto document, possibly less if a sufficient volume of material is handled. Further information may be obtained from the Hon. Secretary, Research Co-ordination Committee, 35 Gordon Square, London, W.C.2.

Old Science and Medicine

E. P. GOLDSCHMIDT AND CO., LTD., of 45 Old Bond Street, have recently issued three catalogues entitled respectively "Science and Medicine", "English Science and Medicine" and "Old Medical Books". The first catalogue contains entries of a complete set in thirteen volumes of Johann Peter Frank's "Complete System of Medical Polity", the first edition of De Kampelen's works on the talking machine, the first German edition of Kepler's "Steriometria" and numerous original papers by Pasteur, Scheel and others. In the catalogue on "English Science and Medicine" we note the rare third edition of Harvey's "De Motu Cordis", Gilbert's "De Magnete", several works by Robert Boyle, including that on "The Mechanical Origine of Production of divers particular Qualities . . . of Magnetical Qualities", the first work on electricity in English, the first edition of Sir Robert Dudley's "Arcano del Mare", one of the foremost English works on navigation and several modern works by Huxley, Galton, Rutherford, Banting and Best, among others. Among the most notable works in the catalogue of "Old Medical Books" are the first edition of John Vigo's treatise on surgery in black letter (1543), the first illustrated edition of Dioscorides (1543), Sir Theodore Turquet de Mayerne's work on arthritis (1676), and the first editions of Laennec's book on auscultation (1819) and Semmelweis's on puerperal fever (1861).

Eclipse of the Sun on April 19

AN annular eclipse of the sun, partly visible as a partial eclipse from the British Isles, occurs on April 19 next. The annular phase is visible in Alaska and the Arctic Ocean. At Greenwich, the eclipse begins at 17^h 29^m, the greatest phase (0.36) being reached at 18^h 18^m; sunset is at 19^h 2^m, just before the eclipse ends. The position angle of first contact is 298° from the north point of the sun's image or 258° from the vertex. At Edinburgh the corresponding times are: beginning 17^h 17^m; greatest phase (0.44) at 18^h 12^m; ending at 19^h 3^m. The above times are in Universal Time; add 1 h. to convert to Summer Time.

The Night Sky in April

THE moon is full on April 4 at 4.3^h and new on April 19 at 16.6^h. The altitude of the full moon at transit at Greenwich on April 5^d 0^h 43^m is 27½°. Lunar conjunctions with the planets occur as follows: on April 10 with Mars; on April 16 with Venus; on April 17 with Jupiter; and on April 18 with Mercury. On April 22, Venus is in conjunction with Jupiter, the geocentric separation of the planets being only 0.4°. The two planets rise, however, less than one hour before the sun. Mercury is at inferior conjunction with the sun on April 3 and is therefore not visible. Saturn is in conjunction on April 11 and likewise rises and sets with the sun. Mars still remains a morning star, rising about 1½^h in mid-April. The only bright stars occulted during the month are ϕ Ophiuchi (mag. 4.6) on April 8 at 2^h 2.9^m (reappearance) as seen from Greenwich, and 26 Geminorum (mag. 5.1) on April 24 at 22^h 12.1^m (disappearance). The Lyrid meteors, the radiant of which is near 104 Heroulis, are due at their maximum between April 19 and 22, but in some years they are nearly absent. All the above times are given in universal time (U.T.). Summer Time begins on April 16.

Announcements

MR. J. E. MONTGOMERY has been appointed secretary of the Institution of Mechanical Engineers in succession to Brigadier-General Magnus Mowat, who has retired on account of ill-health. Mr. Montgomery has been assistant secretary of the Institution since 1920.

THE Rockefeller Foundation has announced that during the next seven years it will grant a sum not exceeding £12,000 to the Imperial College of Science and Technology, South Kensington, for research on vitamins, sterols and related compounds under the direction of Prof. I. M. Heilbron.

AN Institute for Research in Aeronautical Medicine has recently been founded at Mount Fuji, Japan.

IN 1938 the number of deaths in France was 40,000 higher than the number of births, while in Italy the births exceeded the deaths by 424,000 and in Germany by 500,000.

THE University of Peiping, which was closed at an earlier stage of the Sino-Japanese War, has recently been reopened under the direction of Prof. Hisomu Nagat, formerly of the University of Formosa.

WE have received a part of the *Collection Scientifique* issued by the Institut Internationale de Coopération Intellectuelle (1938), entitled "Les déterminations physico-chimiques des poids moléculaires et atomiques des gaz", price 45 francs. The volume contains papers by Moles, Whytlaw-Gray, Cawood, Keesom and others, a long discussion and addenda.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 524.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Atomic Numbers of the So-called Transuranic Elements

We have recently had the opportunity of obtaining a very strong preparation of the so-called transuranic elements, which are precipitated with platinum as sulphide in acid solution, from roughly 100 grams of uranium, after an irradiation with the neutrons of ($^7\text{Li} + ^2\text{H}$) carried out for us in the Cavendish High-Voltage Laboratory. A deuteron current of 100 $\mu\text{a.}$ at 900 kv. was employed over a period of several hours, and the source of neutrons and the uranium were surrounded with a large amount of paraffin so that 'thermal' as well as fast neutrons were effective in the transformation.

The platinum precipitate, weighing less than 20 mgm., separated four days after the irradiation, was examined in a tube counter filled with xenon and alcohol vapour. The counter was fitted with a thin mica window at one end, and roughly 20,000 impulses per minute were recorded with the bare source 2 cm. from this window. When the β -particles were absorbed in graphite, roughly 425 impulses per minute remained. Absorption measurements using aluminium, copper and lead showed that, of these, more than a hundred impulses per minute were to be attributed to a quantum radiation in the ordinary X-ray region.

Further measurements were then made with thin foils of molybdenum (42), palladium (46), silver (47), cadmium (48), indium (49) and tin (50). In this range of elements, a large increase in transparency was observed between indium and tin; 30 mgm./cm.² of tin reduced the counting rate by 36 per minute, whereas the same mass per square centimetre of any of the other elements produced a diminution which was almost twice as great. The simplest interpretation of this result is that a quantum radiation of wave-length between 0.443 Å. and 0.424 Å., the wave-lengths corresponding to the K absorption energies of indium and tin, is emitted by the source. According to the tables of natural X-radiations, the $K\alpha$ -radiations of iodine alone lie in this interval of wave-length. Again, then, the simplest supposition to make is that the element iodine is, in fact, one of the bodies present in the platinum precipitate, being formed from tellurium by β -transformation.

According to previous results¹, our precipitate contained only the radioactive bodies of half-value periods 66 hr. and 2½ hr. respectively. We therefore investigated chemically the suggestion that these bodies are in reality isotopes of tellurium and iodine. Strong confirmation was obtained from the fact that we were able to concentrate the activity of shorter period in a precipitate of silver iodide. On the basis of these results, it is very unlikely that any of the active products hitherto separated with platinum from irradiated uranium is a true transuranic element;

rather must they all be regarded as originating in a similar process of nuclear fission to that in which the barium and lanthanum bodies have recently been shown to arise.

These results had been obtained when the *Physical Review* of February 15 was received in the laboratory. It is of interest to remark that Abelson² there records similar observations, made some time earlier than ours, and draws similar conclusions from his observations.

Transmutation of Uranium and Thorium by Neutrons

It has been shown by Hahn and Straßmann¹ that uranium bombarded by slow neutrons forms a radioactive noble gas. We repeated their experiments, using the very strong neutron source of the Philips X-Ray Laboratory. About 500 cm.³ of a saturated solution of uranyl nitrate was irradiated. Air was bubbled through the liquid at a rate of 600 cm.³ per minute, then it passed through a tube filled with cotton-wool (length 15 cm.) and through a wash-bottle containing 40 cm.³ of water with a small amount of nitric acid and one drop of ammonia. After adding caesium, rubidium, barium, strontium and lanthanum salts we obtained from the contents of this wash-bottle radioactive substances which could be precipitated together with caesium, rubidium and barium.

Caesium, precipitated after 15 minutes with antimony chloride dissolved in hydrochloric acid, showed periods of 10 minutes, 30 minutes and a longer period. Precipitating the caesium from the solution 45 minutes after the irradiation had been finished, we obtained the 30-minute period only.

Rubidium was obtained by precipitation with a saturated solution of sodium bitartrate, dissolving the precipitate in dilute hydrochloric acid and adding perchloric acid. Occasionally the precipitation of the bitartrate was repeated in order to remove traces of caesium. A period of 16 ± 2 minutes was found. As the decay curve has a shape quite different from that of the caesium precipitate (neither a shorter nor a longer period was observed), this activity cannot be ascribed to small amounts of caesium.

We looked for a short period in precipitates of the mixed alkali perchlorates prepared in a very short time. A period of 1-2 minutes was observed. We could not determine whether this activity is due to caesium or rubidium.

Barium, precipitated as a sulphate or as a chromate, showed a period of 87 ± 1 minutes. After prolonged irradiation a much longer period was also observed. No short period was found when the isolation was carried out within a few minutes. By varying the time of irradiation it was shown that the 87-minute period is not produced by the alkali with a period of 1-2 minutes. From the fact mentioned above that the 30-minute period in caesium is not accompanied by a longer period, it follows that the 87-minute activity does not arise from this caesium either. Therefore we conclude that the 87-minute period is produced by the 10-minute activity of caesium, which is in good agreement with the fact that in the caesium precipitate a period of approximately this half-value was observed.

Strontium, which we freed from barium by treatment with chromate and precipitated as strontium sulphate, was found to be inactive after an irradiation of 100 minutes. Precipitates of mixed strontium and barium sulphates prepared in a very short time did not show any short-period activity.

In order to obtain a rough value for the half-life of xenon, we passed the air at a measured rate through two wash-bottles in succession. From the velocity of the air and a comparison of the activities of the caesium obtained from the two bottles, we calculated the average period of xenon effective in producing radio-caesium to be of the order of half a minute. From this experiment we were able to deduce the optimum air-flow.

From the presence of both caesium and rubidium in the wash-bottle, it follows that xenon as well as krypton escape from the uranium solution bombarded with slow neutrons. This indicates that the uranium nucleus may break up in different ways. Radio-xenon gives rise to at least two kinds of active caesium with periods of 10 minutes and 30 minutes. The caesium with the 10-minute period forms radio-barium with a half-life of 87 minutes. The longer barium period is probably produced from the caesium with a half-life of 30 minutes. We carefully compared the barium period of 87 minutes with that produced in barium by neutron capture and found them to be identical. Moreover, we compared the absorption curves of the beta-rays in aluminium as measured with two Geiger counters in coincidence arrangement. We found a perfect agreement.

Active krypton forms radio-rubidium with a period of 16 ± 2 minutes. Probably this period is due to the known radioactive rubidium isotope obtained from rubidium by neutron-capture. The half-life of the latter we found to be 17 ± 2 minutes. In this connexion, it may be mentioned that from uranium bombarded with neutrons Curie and Savitch¹ obtained precipitates of alkali salts showing a period of 18 minutes.

Based on the experiments described we suggest the following processes:

Corresponding experiments with a concentrated solution of thorium nitrate irradiated with the fast neutrons from a (Li + D) source also resulted in the production of a radioactive gas. Preliminary measure-

ments showed that at least three periods occur in the alkali precipitate. The precipitate of strontium and barium sulphates was found to be radioactive too.

In order to check our observations, we collected the radioactive atoms from uranium on filter-paper in a way analogous to that described by Joliot². The irradiations ranged from 15 minutes to 20 minutes. The filter was boiled in a solution containing caesium, rubidium, barium, strontium and lanthanum salts. The alkali perchlorates precipitated from this solution showed a short period of 1-2 minutes and at least one longer period. Barium chromate obtained from the solution showed periods of 12 ± 2 minutes and 87 minutes. The strontium proved to be active too.

We succeeded in measuring the 1-2 minute period more easily without a chemical separation by covering the filter paper with a layer of 4 mm. of aluminium.

It is interesting to observe that the 12 ± 2 minute period in barium was not obtained from the gas. This suggests that it may be formed together with krypton, unless it arises from a very short-lived xenon period or from caesium formed directly from uranium.

An attempt to activate uranium with the gamma-rays from lithium bombarded by protons gave no result. A search for electrons having an energy exceeding 10 Mev. during the irradiation of uranium with slow neutrons using two Geiger counters in coincidence arrangement was unsuccessful.

Chemical Separation of Isomeric ⁸⁰Br Atoms

FOR rather more than a year, we have been studying the concentration of radiobromine by modifications of the method of Seillard and Chalmers¹, and have been using concentrates to follow the kinetics of exchange reactions between radiobromine ions and alkyl bromides. In the course of this work, we have encountered a number of puzzling phenomena which are now completely explained by the remarkable discovery made by Segrè, Halford and Seaborg² and DeVault and Libby³ that the isomer of ⁸⁰Br with a half-life of 4.5 hours decays by a γ -ray change to an isomeric ⁸⁰Br which emits β -rays with a half-life of 18 minutes. The recoil from the soft γ -ray emitted by the parent nucleus (and its internal conversion) has been found sufficient to break a chemical bond in the BrO_3^- anion or to activate the C-Br bond in *tert*-butyl bromide and facilitate the hydrolysis of this compound. These reactions have been used to separate the isobaric 18-min. product from its parent 4.5-hour isomer with which it was previously in radioactive equilibrium. The β -ray activity of the daughter isotope in the reaction product was found to decay with a half-life of 18 min., whilst the activity of the residual bromine in the original reaction increased with time as the equilibrium concentration of the 18-min. isomer was restored by decay of the parent.

The purpose of this note is to record some of our observations which confirm the results of the workers at Berkeley. We have found that the addition of a few per cent of aniline (other nitrogenous organic bases behave in a similar manner) to an organic bromide before irradiation with slow neutrons gives a large increase in the amount of radiobromine which can be extracted afterwards by water or aqueous acids. In this case it is the capture γ -rays which disrupt or activate the C-Br bond and facilitate the reaction

This reaction can also give a large separation of the ^{82}Br isomers, as the following experiment shows.

Pure ethylene dibromide was irradiated with slow neutrons (from 200 mgm. radium sulphate plus beryllium) for 15 hours. Five per cent of aniline was then added and the mixture shaken with water at intervals until five hours had elapsed. By this time all the 18 min. isomer originally present would have decayed. After a final wash, the β -ray activity of the specimen was followed for 45 min., with the result shown in the accompanying graph. The initial

activity found was largely due to ^{82}Br with a half-life of 36 hours; this was measured after the shorter lived products had completely decayed, and the data in the graph are corrected for this activity. If the separation of the ^{82}Br isomers were complete, the initial activity would be zero. The full line in the figure represents the calculated curve for 90 per cent separation: it will be seen that the reaction of salt formation with aniline gives a separation of this order of magnitude. The activity in the aqueous extract was found to decay with a half-life of 18 min.

In our kinetic studies alkyl bromides, notably *n*-butyl bromide, were allowed to interact with radioactive bromine ions in a solvent consisting of 90 per cent acetone and 10 per cent water. At the end of the reaction the alkyl bromide was separated by dropping a portion of the mixture into water and extracting with benzene. When working with bromine of which the activity was mainly that due to the 4.5 hour period, we have repeatedly found that the β -ray activity of the benzene solution increased 20 per cent or more during the first hour after washing with water, whilst a reference specimen of the acetone solution decayed normally. This effect was not observed during the study of slow reactions in which

the activity was measured after two to three days and was entirely due to ^{82}Br (36 hours). Hence the hydrolysis of *n*-butyl bromide under the conditions of our experiments also gives a considerable separation of the isomeric ^{82}Br atoms.

Structure of Meteorites

Prof. E. A. Owen and R. W. Williams¹ have recently advanced a theory in which they account for the Widmanstätten figures in meteorites on the basis of their X-ray studies of iron-nickel alloys, natural and artificial. Their conclusions have been criticized by Prof. S. W. J. Smith and J. Young² on the grounds that only the surface of the meteorites is heated by passage through the earth's atmosphere. This criticism must not be allowed to detract from the merits of the experimental evidence given by Owen and Williams, which to a large extent receives confirmation from an investigation I have recently carried out with Mr. Goldschmidt.

X-ray powder photographs show that the iron-rich end of the nickel-iron equilibrium diagram must be completely redrawn. The areas of single phase and two-phase equilibria shown in the figure are based on the results of long periods of heat-treatment, and cannot be attained by cooling at the usual rates. Some idea of the times required even under the most favourable conditions is given by the time-scale attached to the diagram. Shorter times of annealing give entirely different results. There is not space here to give the evidence on which this diagram is based, or to explain its details. The purpose of this communication is to show how it affects the problem of the meteorites.

The new diagram confirms Owen's conclusion that suitable heat-treatment leads to the production of a two-phase structure in certain alloys. A typical meteoritic structure, which consists of a mixture of kamacite (body-centred cubic with 8 per cent of nickel) and taenite (face-centred cubic with about 26 per cent of nickel), is the equilibrium state at temperatures between 350° and 580° C. The existence of pleonite in some meteorites may perhaps be explained as due to sudden cooling from above 580° C., leading to a deformed body-centred cubic structure produced by a sudden breakdown of the face-centred cubic form, though other explanations are possible.

Up to this point Owen's results are confirmed. There are, however, two important features of his theory which require modification.

(1) It must be concluded from the criticisms advanced by Smith and Young that the heat-treatment by which the meteorites received their characteristic structure occurred before they reached the earth and was not substantially modified by passage through the earth's atmosphere.

(2) Our diagram indicates that a further transformation not mentioned by Owen occurs at 350° C. or thereabouts. The typical meteoritic structure is

only in equilibrium between 350° and 580° C., and not below 350° C. Such meteorites must therefore have received their heat-treatment above 350° C. They must have cooled too quickly for equilibrium conditions to be followed down to terrestrial temperatures; at such temperatures they are too sluggish for further changes to take place.

The $\alpha + \gamma$ structure formed in the temperature range between 350° and 580° C. requires a time of the order of months to break down when the temperature drops below 350° C. Breakdown takes place, for example, when the cooling rate is about 1° C. per day, not for more rapid rates. The transformation to $\alpha + \gamma$ at 580° C. is also slow, but not so slow as the lower transformation. At a cooling rate of 100° C. per day this reaction is just beginning to go. The conclusion seems to be that the meteorites have cooled at some intermediate rate, slow enough to permit the 580° C. change to take place, but too fast for the 350° C. transformation.

Before deciding when and where this cooling took place, it is important to consider another fact. A single cooling, though satisfactory for the production of small submicroscopic crystals such as are found in our experiments, would be totally inadequate to give the large crystals found in meteorites. It must be concluded that the process has been repeated thousands if not millions of times.

Is it possible that some meteorites were bodies in cometary orbits, and they have been heat-treated by approaching the sun and cooled by moving into the outer parts of the solar system? The cooling rate seems quite reasonable, the short time in which the meteor is near the sun being quite inadequate for the attainment of equilibrium below 350° C., though it may well be sufficient to promote crystal growth at higher temperatures. The meteorite is subjected to fresh heat-treatment every time it reaches the neighbourhood of the sun, but the most effective part of this treatment is that which takes place in the $\alpha + \gamma$ range; as the crystals grow, it becomes increasingly difficult for the 350° C. transformation to take effect.

This explanation is applicable to meteorites in which the tenite phase has a composition of about 26 per cent nickel. For example, the San Cristobal meteorite with 26.3 per cent of nickel is mostly

tenite with patches of plessite. The structure of other meteorites in which the tenite contains more nickel must have been produced in other ways. Prof. S. W. J. Smith and J. Young have recently described such a case¹.

'Intraglobular' Reactions and the Cyclol Structure of Proteins

In order to explain the effect of a protein on a certain condensation reaction, Talmud¹ has proposed a hypothesis for 'intraglobular' reactions, based upon Wrinch's well-known theory² of protein structure. As an example, he showed that a considerable portion of 2-5-dioxopiperazin formed by condensation of glycine ethyl ester³ in an aqueous solution of egg albumin remains in solution associated with the protein, in excess of the normal solubility limit. Talmud suggests that the reaction has taken place in large part within the hollow cyclol globules, and that the reaction product is prevented from diffusing out owing to its molecular size. By independent adsorption experiments (on heat-denatured egg albumin at 0°) Talmud believes he has shown that the amount of dioxopiperazin remaining in solution was in excess of the amounts that could be adsorbed on the surfaces of the globular protein molecules.

We have measured the sedimentation constant and the diffusion constant of the egg albumin-dioxopiperazin complex in order to get an estimate of its size and shape. The sedimentation constant was measured both in the water-alcohol-dioxopiperazin medium formed by the reaction, and in a solution dialysed against 0.2 M sodium chloride. Within experimental errors, we always obtained the same value. The average was 3.62 (sedimentation constants are given in units of 10^{-13} ; diffusion constants in units of 10^{-7} throughout), which is a little higher than for ordinary egg albumin⁴ (3.55). This fact possibly indicates that the glycine ethyl ester has replaced some of the water bound to the molecule. The diffusion constant was found to be 6.6, as an average of three experiments. For ordinary egg albumin the value⁴ is 7.76. The reduction of the diffusion constant indicates an increase of the volume of the particle, probably by interaction between the glycine ester and the free amino or carboxyl groups on the surface of the protein molecule. According to Talmud's theory, there should be no change in the volume of the complex particle, because the dioxopiperazin molecules are retained inside the globule after the 'intraglobular' reaction.

Talmud found precipitation on prolonged dialysis against pure water, probably due to denaturation. We found no difficulty in dialysing against salt solutions. When dialysing against water, a small precipitate formed, but most of the complex remained in solution and showed the same sedimentation constant as before dialysis.

Our experiments seem to show that the egg albumin-dioxopiperazin complex can be considered as a chemical compound, in which glycine residues, $-\text{HN} \cdot \text{CH}_2 \cdot \text{COOH}$ or $-\text{CO} \cdot \text{CH}_2 \cdot \text{NH}_2$, are bound to the hydroxyl groups or the free amino groups of the

protein. One might also suppose that one glyceme molecule might be bound to another one already combined with the protein. It is not clear why such reactions should be slower than the formation of dioxopiperazin from glycine ethyl ester. The 'intra-globular' accumulation of dioxopiperazin molecules should have given a higher sedimentation constant (calculated from Talmud's figures, $s = 4.02$) than we found. Talmud assumed that the whole volume of the egg albumin molecule could be filled with dioxopiperazin molecules. This disregards the volume taken up by the protein itself. The space available for non-protein materials inside the presumed globule must be much less than the total volume of the protein globule. The low value found for the diffusion constant probably must be explained by outside bound groups. If one presumes the egg albumin molecule to be spherical (which is very nearly true) and the bound groups to be placed symmetrically around it, the reduction of the diffusion constant from 7.76 to 6.6 means an increase of about 60 per cent in the volume.

It is therefore obvious that Talmud's experiments cannot be taken as an experimental proof of Wrinn's hypothesis, although they may be of interest for the understanding of protein structure and protein synthesis.

Spontaneous Coagulation of Rubber Latex

So early as 1913, Whitby advanced the view that spontaneous coagulation in rubber latex takes place before decomposition processes begin¹. Arguments against this view have since been advanced by several investigators, and the opinion at present generally held is that the coagulation of fresh latex is caused by formation of acid from the bacterial decomposition of the serum constituents.

Recent investigations made on latex of *Hevea brasiliensis* have provided confirmation of the view held by Whitby. Experiments were conducted throughout on latex obtained immediately after collection from the trees, which had been tapped three or four hours previously. The formation of ions from decomposition of latex was followed by conductivity measurements. The conductivity of latex did not change until coagulation was complete. This occurred 6–11 hours after collection of the latex, varying from sample to sample. The resistance of the conductivity cell increased after gel formation due to contact resistance on the electrodes.

The pH after coagulation (measured by Lyphan indicator strip) was only 0.2 lower than the average original figure of about 6.4. Decreasing the pH below 6 by the addition of phthalate-KOH buffer solutions had no effect on the rate of coagulation of the samples. After coagulation decomposition of latex constituents proceeds; but this bears no relation to the process of coagulation which is already complete.

Further support of Whitby's view was provided when strong antiseptics preventing bacterial decomposition were added to fresh latex without preventing spontaneous coagulation. The addition of 0.3 and 0.4 per cent sodium pentachlorophenate had no influence on the behaviour of latex as described. No decomposition nor any change in the pH value of 7 could be found in coagulated samples which were measured over a period of 3–8 weeks.

The exact nature of this process of coagulation is not known; enzymatic action on proteins may, however, be put forward as an explanation.

Demonstration of the Participation of Free Radicals in the Rearrangement of Benzyl Phenyl Ether

It has been shown previously¹ that when benzyl phenyl ether is heated in quinoline at about 250°, the normal rearrangement of the ether to *o*- and *p*-benzyl phenols is accompanied by the formation of benzylquinolines and of toluene. It is now found that hydroxyphenyl quinolines are also products of this reaction, and that it is possible, by a careful control of the experimental conditions, to increase very considerably the yields of benzylquinolines and hydroxyphenyl quinolines at the expense of the normal products of the rearrangement.

This new evidence strongly supports the contention that the preliminary phase of the reaction is a dissociation of benzyl phenyl ether into benzyl and phenoxy groups. As both these groupings are found to attack the same positions in the quinoline nucleus, it seems unlikely that they react as ions having opposite charges. This result is consistent only with the view that the reactive centres of both groups are in the same electronic state². This can only occur if the ether dissociates into free radicals.

This conclusion does not require the assumption of any special reaction of free radicals, except their ability to replace the hydrogen of the aromatic nucleus; it is based on experimental evidence which is considered to afford an independent and reasonably satisfactory demonstration of the existence of free radicals of short life in solution.

An extension of this investigation to other rearrangements is now in progress.

A Fluoride with Pyrochlore Structure

THE formula of the rare mineral rastonite is usually written $(\text{Na}, \text{Mg})\text{F}_3 \cdot 3\text{Al}(\text{F}, \text{OH}) \cdot 2\text{H}_2\text{O}$. This implies a replacement of Na by Mg . X-ray investigation of this mineral shows that it belongs to the space-group $\text{O}_h^1 - \text{Fd}3m$ and that the edge of the unit cube has a length of 9.87 Å. By recalculation from the best available analysis (Penfield and Harper, 1886), it can be shown that a unit cube contains on the average 48 (F, OH), 16 (Al, Mg), 2.7 Na and 7 H_2O . The structure is similar to that

of the pyrochlore group (type $E 8_1$) for which the formula $X_2Z_2(O,OH,F)$, has been written. In the case of ralstonite the X position (16c) is only partly filled by 2.7 Na. Water partly fills the 8b position which is occupied by O, OH or F in minerals of the pyrochlore group.

Ralstonite may be dehydrated without destruction of the crystal lattice.

A Visual Phenomenon

MR. DARTNALL¹ has recently described an interesting visual phenomenon which, as has been pointed out by Mr. Wright², is connected with the after-images of different colours possessing different rates of development. A visual phenomenon possibly connected with this differential rate of development came to my notice some time ago, and no doubt must have been observed by others as well. A stroboscopic disk painted in black and white sectors is run under illumination from an (ordinary) Osram neon lamp connected to a.c. supply (80 cycles). At speeds such that the pattern is not stationary but somewhat shifting, the white sectors appear to be distinctly coloured (rainbow type)—one edge pink and the other green. The same effect is seen, though not so clearly, when the neon lamp is replaced by an ordinary incandescent lamp, provided the illumination is not high.

Changes in the Water-Content of Organs and Tissues as a Result of Stimulation by Oestradiol

APART from its specific property of stimulating proliferation in the reproductive tract and in certain other tissues of the body, oestrogenic hormone has the more general effect of causing water and salt retention. This was clearly demonstrated in the follicular phase of the menstrual cycle in the pig-tailed monkey¹ and baboons², and in rhesus monkeys which had been injected with oestrogenic hormone^{3,4}. In these animals, water-retention is most obviously related to swelling of the sexual skin, and it may be associated with a marked shift of body water (as shown, for example, by changes in erythrocyte concentration)^{3,4}. Study of the renal excretion of electrolytes has shown that water-retention also occurs in male dogs after treatment with oestrogenic substances⁵, while more recently Astwood⁶ has reported that the water-content of the uterus of the rat undergoes a transient rise which reaches its peak six hours after a single injection of oestrogenic hormone, returning to normal about twelve hours after the injection.

A further study of immature rats shows that

oestrogenic stimulation causes a rapid change in water-content not only in the reproductive tract but also in most organs and tissues.

Estimations of the water-content of nine selected tissues were made at six-hourly intervals after the subcutaneous injection of 0.1 γ of oestradiol in 0.1 c.c. of oil. Water-content was determined by comparing the weight of the fresh tissues with their weight after desiccation in an oven at 110° C. Ten rats were used for each six-hourly reading.

The tissues were divided by their responses into two clearly defined groups, the first being made up of the skin, uterus and vagina, and the second of striated muscle, heart, pancreas, brain and gut.

Water-content in the first group of tissues reached a high level by the end of the first six hours. It then fell (in the case of the skin and vagina to a lower level than normal) and remained down until the twenty-fourth hour, when it rose again to remain at a high level until the sixty-sixth hour. By the seventy-second hour, it had either resumed its normal level or fallen below it.

The changes in the second group of tissues (striated muscle, heart, brain, pancreas, gut) were in a sense reciprocal to those in the first. In the first twelve hours after injection, water-content either fell or remained unaffected. It rose to a level above normal during the period (twelfth to thirtieth hours) in which the water-content of the first group of tissues was low. It then decreased and reached a minimum about the middle of the second and more prolonged period in which the water-content of the reproductive tissues and skin was high. At the end of this period it underwent a sharp transient rise, before reaching its normal level, or a lower level than normal, at the seventy-second hour. Corresponding observations have been made on normal and castrated male rats injected with oestradiol, as well as on normal mice in oestrus and in dioestrus, the latter observations showing that cyclical changes normally occur in the water-content of the tissues referred to above.

These findings show that oestrogenic stimulation causes a much more widely spread change in the body than has been suspected hitherto. In the case of the skin, the total amount of water-shift amounts to almost one per cent of the total body-weight (estimation based on tables provided by Donaldson⁷). A change of this kind and magnitude cannot be regarded as secondary to changes in water-concentration occurring primarily in the reproductive tract, and presumably, therefore, oestrogenic stimulation has a direct effect on the water-content of many, if not of all, tissues.

In so far as oestrogenic substances lead to water- and salt-retention, they behave like the chemically related substances progesterone and testosterone, as well as like desoxycorticosterone. This general property of the sterol hormones does not, however, imply a similarity of action. Thus nitrogen-retention is associated with the water- and salt-retention stimulated by oestrogenic and androgenic substances, whereas it does not occur as a result of the action of progesterone and desoxycorticosterone⁸. Furthermore, it has been shown that the excretion of water which has accumulated in the sexual skin of monkeys under the influence of oestrogenic stimulation cannot be prevented by the administration of progesterone, testosterone, or cortin⁹. Preliminary observations on the effect of these substances on female and male rats, made in the course of the present study, suggest

that, while changes in water-content occur in all the tissues studied (the changes being especially pronounced in the skin), their character and time-relations are not the same as those which occur after oestrogenic stimulation.

A Humoral Transmission of Muscular Contraction in the Presence of Veratrine

THE hind limbs of a Hungarian frog are perfused with veratrine 1/50,000 in Ringer's solution. The liquid collected from the vein perfuses a second, similar Trendelenburg's preparation. Direct tetanic stimulation of the hind limbs of the first frog is followed, after a latent period of about 10 minutes, by an irregular contraction of the perfused muscles of the second frog. It is thus possible to demonstrate a humoral transmission of the contraction in the presence of veratrine.

This effect is not due to acetylcholine, because (1) veratrine has no anticholinesterase action (Bacq and Brown), and (2) the transmission is still demonstrable in the presence of curare.

We think that the substance responsible for the effect is the K ion, because (1) veratrine, even in 1×10^{-6} solution, greatly sensitizes frog's muscle to the action of K^+ , and (2) the addition of a small amount of potassium chloride (0.5 mgm.) to an inactive perfusate (2.5 c.c.), collected in absence of stimulation, reproduces perfectly the action of a 'stimulation' perfusate. This quantity of potassium can actually be liberated during a tetanic contraction.

Role of Fungi and Actinomycetes in the Decomposition of Cellulose

WAXSMAN¹ has recently demonstrated, by cultural methods, the important role of fungi and actinomycetes in the breakdown of plant tissues in composts and dunghills. The details of the process, however, were not directly observed. I have previously^{2,3} described methods, involving the use of polarized light, for the direct microscopical observation of the cytolastic process in the caecum and rumen of herbivora. These methods have since been applied to the study of the decomposition of vegetable materials in animal faeces, composts and dunghills. The role of Fungi and Actinomycetes in the breakdown of cellulose thereby immediately became conspicuous. Disintegration of the cell-wall constituents was directly evidenced by loss of double-refraction and by

disappearance of microchemical reaction in the affected structures.

The characteristic features which attend the excision of enzymatic cavities by fungi have been described by Bailey⁴; so that it is possible readily to distinguish the changes taking place from those produced by bacteria.

(a) Prosenchymatous fibre invaded by mycelium. Note destruction of secondary and persistence of primary and tertiary layers of wall. Polarized light. Crossed Nicols. $\times 400$. Composted material.

(b) Plant hair, late phase of attack. Note formation of conical and bloom-like enzymatic cavities (cf. Bailey⁵). On right, complete dissolution of secondary wall. Primary wall still intact. Tertiary wall in process of disintegration. Crossed Nicols. $\times 400$. Horse faeces *in vitro*. 2 months.

(c) Another portion of same hair. Earlier phase of attack. Breakdown of channels by fungus filaments. The advancing tip of a hypha can be clearly seen slightly right of centre. Crossed Nicols. $\times 400$. Horse faeces *in vitro*. 2 months.

(d) Enzymatic cavity in hair. Polarized light. Note entire loss of double-refraction $\times 600$.

(e) Identical specimen plus chloroform. Note absence of microchemical reaction in the enzymatic cavity. In both d and e the relative immunity of primary and tertiary layers can again be observed.

DISINTEGRATION OF CELLULOSE IN ANIMAL FAECES AND COMPOSTS.

Details of the process of infection and attack are now under investigation. Abundant infection of the lumen can commonly be demonstrated in prosenchymatous tissues. Rigid unbranched and extremely attenuated hyphae are there formed which from point-to-point penetrate the tertiary layer of the wall through fine rectilinear channels. In the secondary layer these hyphae expand and branch repeatedly; their proliferation being accompanied by an active excision of enzymatic cavities. The disorganization of the tertiary layer, on the contrary, is delayed until a later phase in the process; whilst the primary layer may in some cases entirely resist destruction. This resistance is due to the impregnation of the cellulose substratum by encrusting

substances the presence of which can be demonstrated by extraction with solvents and by microchemical reactions. In this way it can be shown that the cytotoxic process may be highly selective; and that the changes occurring, for example in composts, may bear reference to the balance of cell-wall constituents in the materials employed.

The accompanying photomicrographs illustrate some of the salient features in the changes described above.

Hybrid Vigour in the Tomato

THE vigorous growth of hybrids between closely related varieties has been widely observed, and for several years the phenomenon has received the attention of geneticists. Investigations have also been made on the physiology of hybrid vigour (heterosis). Ashby¹ and Luckwill² have shown that in the tomato heterosis is manifested at an early stage in the life-history, between fertilization and seed ripening, so that the ripe hybrid seed, resulting from cross-pollination, is larger and heavier than that of the parent strain. In a recent experiment a different result has been obtained, and the causes of this contradiction have been investigated.

Two lines of tomato (105 and 107) were crossed in both directions and also *artificially* self-pollinated. Fruits were killed and fixed at different times after pollination and the seeds and embryos measured. If the development of the hybrid embryo is compared with that of the selfed maternal parent, it is found that in each case the hybrid embryo is significantly larger in the earlier stages of development, but that this initial advantage is not maintained. In the ripe fruit the hybrid embryo is the same size as the embryo of the selfed maternal parent. This is illustrated in the accompanying graph. The final size of the reciprocal hybrid embryos, which are of identical genetic constitution, is significantly different, and is evidently determined by the maternal parent. The final size of a hybrid embryo is thus no criterion of the degree of heterosis. The results for the size of the whole seed were exactly similar, and this agrees with the fact that, in the tomato, seed size and embryo size are highly correlated.

The relation of the embryo to the fruit is a double one. Development of fruit and size attained depend on the presence of growing embryos: but the size of seeds is also determined or limited by the nutritive supplies from the fruit. In this investigation of the tomato it was found that 'fruit weight' was highly correlated with 'seed number' (0.735 ± 0.041) and this confirms the first relation. Also 'mean seed weight' was directly correlated with 'fruit weight/seed number', that is, 'fruit weight per seed' (0.580 ± 0.061). This illustrates the second. It may be said, therefore, that the 'mean seed weight'

MATERNAL INFLUENCE ON EMBRYO DEVELOPMENT.

A. 107 and (107 × 105). B. 105 and (105 × 107).

● Parent embryos; ■ hybrid embryos.

is determined primarily by the number of seeds which chance to develop in a fruit.

In a further experiment with the tomato, the seeds of hybrids were compared with those of the selfed parent, the more usual technique of allowing self-pollination to take place *naturally* being employed. In the hybrids (*artificially* pollinated) the seed number was lower and the value of fruit weight/seed number much higher. The mean seed weight of the hybrid was greater than that of the selfed parent. Data are given in the following table.

	Parent 107 Natural pollination	Hybrid 107 × 105 Artificial pollination	Ratio hybrid parent
Mean seed No.	207	143	
Mean fruit wt. per seed	0.564	0.702	1.27
Mean seed wt. (mgm.)	3.065	3.866	1.27

This is the result obtained by Ashby and Luckwill. It is clear, however, that the greater seed size is not due to heterosis, but to the fact that fewer seeds developed in the hybrid than in the naturally selfed—and therefore more efficiently pollinated—parent. In the embryo development experiment first quoted, where all the progeny were the result of artificial—less efficient—pollination, there is no difference between the seed size of the hybrid and that of the maternal parent.

A Gold Sol Test for Bovine Mastitis

ERADICATION of bovine mastitis is one of the major problems confronting dairy research, and the solution of the problem depends to a large extent on trustworthy methods for detecting udder infections, particularly of the sub-clinical type. Many tests have been proposed, but none appears to compare in reliability with the method of isolating the causative micro-organisms by plating on selected media.

A promising chemical test was recently put forward by Rowland¹ in which the characteristic changes in the percentage distribution of the milk proteins are utilized. Rowland showed that even in sub-clinical mastitis the percentage of casein-nitrogen falls below the normal level. This loss in casein is primarily out-balanced by a rise in globulin, and this suggested the possibilities of working out a method similar to Lange's gold test for cerebrospinal fluid, a test which is largely bound up with pathological changes in the globulin content of this body liquid. Owing to the predominance of casein, no characteristic results could be obtained with whole milk, but a sensitive test was procured with casein-free milk serum prepared in the manner described by Rowland and titrated back with sodium hydroxide, using methyl red as indicator, to a pH in the region of 6.0-6.5. When 5 ml. of a red gold sol prepared in accordance with Lange's directions are mixed with 1 ml. of this serum, the colour of the gold sol remains unaffected by sera from milk of healthy individual cows or quarters,

but turns instantaneously to violet or blue in the case of even slight infection of the udder.

The results so far of this simple and rapid test seem to correlate particularly closely with the bacteriological findings regarding the presence or absence of mastitis-producing organisms in the milk. Experiments with dilution series suggest that the correlation between globulin content or globulin/albumin ratio and the intensity of the colour changes is not of a simple nature, and preliminary investigations indicate that the proteose-peptone fraction of nitrogenous compounds of the milk also participates in the reaction.

A detailed study of all the factors involved is now in progress.

Points from Foregoing Letters

By isolation of the natural *K* X-radiation, and also by chemical tests, it has been shown by N. Feather and E. Bretscher that an isotope of iodine is one of the active products formed by the action of neutrons on uranium, and previously regarded as belonging to a series of transuranic elements.

The formation of radioactive noble gases during the irradiation of uranium with slow neutrons has been studied by F. A. Heyn, A. H. W. Aten jun., and C. J. Bakker. It is shown that the nucleus can be split in different ways, giving rise to either krypton or xenon. Several decay products of these gases are observed. Bombarded with fast neutrons, thorium also is found to form noble gases too.

L. J. le Roux, C. S. Lu and S. Sugden record experiments in which two further reactions (the condensation of alkyl bromides with aniline and the hydrolysis of *n*-butyl bromide) have been used to separate the isomeric ⁸²Br nuclei. These results confirm the discovery of Segrè, Halford and Seaborg and of DeVault and Libby that the ⁸²Br nucleus of period 4.5 hour decays by a γ -ray change to give the isomeric ⁸²Br nucleus of period 18 minutes.

On the basis of X-ray experiments on iron-nickel alloys, A. J. Bradley offers a new explanation of the structure of some meteorites. These bodies may consist of a mixture of large α - and γ -crystals, corresponding to a state of equilibrium at some temperature between 360° and 580° C. It is suggested that they have gradually assumed this state while in the neighbourhood of the sun, which they encircle in a cometary orbit.

N. Gralén and The Svedberg state that sedimentation and diffusion experiments show that the hypothesis proposed by Talmud for 'intraglobular' reactions based upon Wrinch's theory of protein structure cannot explain the formation of a complex between egg albumin and glycine ethyl ester. It is suggested that the complex can be considered as a chemical compound, and with the glycine residues bound on the outside of the protein molecule.

P. Stamberger finds that the coagulation of rubber latex from *Hevea brasiliensis* takes place 6-11 hours

after collection, before decomposition processes have set in. No change in electrical conductivity could be observed during that period. The coagulation is apparently due to the action of enzymes on the protecting proteins.

W. J. Hickinbottom reports that a study of the isomerisation of benzyl phenyl ether in quinoline solution has yielded results which demonstrate that the isomerisation is preceded by an initial fission of the ether into free radicals.

X-ray investigation of the fluoride-containing mineral rastonite shows, according to A. Pabst, that it has a structure similar to that found in the pyrochlore group.

Oestradiol produces in immature rats changes in the water content of most organs and tissues, according to experiments by S. Zuckerman, A. Palmer and G. Bourne. The skin, uterus and vagina show an increase in the water content in the first six hours, then a fall until the 24th hour, and then again an increase until the 66th hour. The water content of the striated muscle, heart, pancreas, brain and gut, on the other hand, changes mainly in the opposite way from that described above.

The fungal disorganization of plant residues in dung and composts has been studied by F. Baker by direct microscopical observation in polarized light. Characteristic disintegration patterns are illustrated. Fungal attack originates in the lumen of fibres, fine hyphae penetrating the tertiary and proliferating in the secondary layer of the wall. The primary layer remains immune from attack.

Some experiments described by E. S. J. Hatcher show that the large hybrid seeds and embryos obtained by crossing two inbred strains of tomato are not the direct expression of hybrid vigour. They are the effect of reduced competition between fewer seeds which are produced by artificial and therefore less efficient pollination.

A new test for bovine mastitis based on a reaction between casein-free milk serum and solutions of colloidal gold is outlined by R. Aschaffenburg.

Research Items

Sarcee Indians of Alberta

As little has been published about the Sarcee Indians, the National Museum of Canada sent Diamond Jenness to a reserve near Calgary to study their old customs and beliefs. The material gathered has now been embodied in a report of the Canadian Department of Mines and Resources (*Bull.*, No. 90, *Anthropol. Ser.* 23, 1938). Though frequently mentioned by European explorers of the eighteenth century, the Sarcee did not become regular visitors to any trading post until the last decade of that century. In the inter-tribal warfare of the earlier nineteenth century, the Sarcee, being one of the weaker tribes, joined themselves to the Blackfoot Confederacy. Throughout the nineteenth century, they suffered much from the effects both of warfare and epidemics, so that by 1924 the number on the reserve had been reduced to 180 individuals only. In physique, mentality and customs they seem scarcely distinguishable from Blackfoot Indians; but they have retained an Athapascan tongue. They were a democratic people, who did not countenance hereditary distinctions of caste or rank. They were divided into bands containing a number of closely related families, that usually hunted together and always camped as a unit when the tribe was united. Girls belonged to their mother's bands; boys above the age of nine or ten years to that of the father, though still retaining close contact with their mother's band. The bands seem to have been very fluid, constant neither in number nor composition. Each band had its leader, who was not elected, but was recognized by common consent because of his prestige. Although he possessed no formal authority, his advice and instructions were rarely disobeyed. Separate from the bands and cutting across them were five societies or clubs, to one or more of which every male Sarcee belonged at some time or other. Each society held an annual four days' dance, being dormant for the rest of the year.

Androgens and the Ovary

M. Mazer and C. Mazer (*Endocrinology*, 24, 175; 1939) have found that, in the immature rat, prolonged administration of the androgen testosterone propionate caused a decrease in the weight of the pituitary, adrenals, ovaries and uterine horns and inhibition of oestrus with mucification of the vaginal epithelium. The degree of uterine atrophy was not in proportion to the ovarian atrophy, probably because the suppression of oestrogen production was partly counterbalanced by the direct stimulative effect of testosterone on the uterus. The adult rat reacted similarly except that the pituitary gland showed no significant decrease in weight. The deleterious effect of prolonged testosterone treatment on the ovaries was temporary. Restitution of structure and function occurred within 20 days. The literature and the authors' experiments showed that the duration of treatment was the determining factor in the effect of testosterone on the ovaries; short treatment produced stimulation and prolonged treatment depression. The ovarian atrophy, in the authors' opinion, was secondary to pituitary inhibition.

Glucose Excretion in Diabetic Dogs

P. Govaerts and P. Muller (*J. Clin. Invest.*, 18, 25; 1939) have investigated the excretion of glucose and creatinine in dogs made diabetic by pancreatectomy. The creatinine clearance being considered as a measure of the glomerular filtration and the glucose concentration of the arterial plasma as equal to the concentration of this substance in the glomerular filtrate, the quantity of glucose which the tubular cells reabsorbed from 1 c.c. of glomerular filtrate could be calculated. This figure was called the 'threshold'. When the blood-sugar concentration increased moderately, this threshold increased, and with further elevation soon reached a maximal value which remained constant for any higher level of glycaemia. In the diabetic dog at high levels of hyperglycaemia, a constant part of the filtered glucose saturated the reabsorptive power of the tubular cells, and the remainder was completely excreted as in a phlorizinized dog. These characteristics of the renal function did not change appreciably in the diabetic dogs during a period of observation lasting several months.

A Fossil Whale from Australia

In the older Tertiary rocks at Torquay, Victoria, B. G. Pritchard and his assistants discovered and collected from a cliff face the greater part of the skull of a zeuglodon whale, described as belonging to a new genus *Mammalodon* (*Victorian Nat.*, 55, 151; Jan. 1939). Various discoveries of fossil whale remains, consisting mostly of teeth, have been made in the Tertiary deposits of Australia since McCoy's first record of *Squalodon* or *Phocodon* from the Miocene of Cape Otway in 1864. But the present find differs from them in the small size and delicate build of the skull and of the teeth and their cusps. Dr. Pritchard considers it to be a very early type of Tertiary whale, "showing the closest approach to descent from a mammalian type of ancestor". The age of the rocks from which it was recovered is a matter of controversy, for they have been attributed to various periods ranging from Miocene to Eocene, but the author favours their Eocene origin.

Reproductive Organs of the Silk Worm Moth

SHINOSUKE ÔMURA has recently issued a notable paper on this subject (*J. Fac. Agric. Hokkaido Imp. Univ.*, 40, Pt. 3; 1938). In so far as the female organs are concerned, the work is directed to tracing the whole history of the spermatozoa from when they are discharged into the bursa copulatrix. It appears that the spermatophore, ejected by a male, occupies the greater part of the cavity of the bursa. Several hours after ejaculation, the spermatozoa fill the receptaculum seminis. They enter the ductus seminalis by their own motility, while their passage along this duct is aided by means of peristaltic movement of its muscular walls. About thirty minutes after mating, spermatozoa were appearing in the receptaculum seminis. The author claims that the sperms enter the receptaculum by its duct, the so-called ductus tortuosus. On the other hand, when they leave the receptaculum, to fertilize the eggs, he states that

they pass down the hitherto unrecognized canaliculus fecundans. Each egg, in its passage to the exterior, passes in such a manner that its micropyle is opposite the opening of the canaliculus into the vestibulum, and in this way becomes fertilized. The average time for laying each egg is only 6.7 sec. As regards the male organs, Omura points out that the ductus ejaculatorius of most authors is divided into three parts, namely, glandula spermatophora, glandula alba and glandula prostatica. The histology of the different parts of the male reproductive system is described and figured while the functions are discussed in some detail. The mechanism of ejaculation, and of spermatophore formation in the bursa of the female moth, is also described. The author claims that the secretion of the glandula prostatica is necessary for the proper functional activity of the sperms. The translocation of the spermatozoa from the testis into the post-testicular parts takes place, it appears, some four days before the moth emerges from the pupa.

Genetics in the U.S.S.R.

In February 1938, a conference on interspecific and intergeneric hybridization, arranged by the Institute of Genetics, was held at the U.S.S.R. Academy of Sciences at Moscow. A hundred and fifty scientific men took part, and more than forty papers were read. Profs. Vavilov, Kostoff and Lusa gave critical surveys of the present-day knowledge of distant hybridization and its importance in the improvement of plants and animals and to a better understanding of evolution. Reports were also made of work on hybridization in cereals, tobacco, fruits, forage crops and potatoes. Work on the crossing of various species of *Agropyron* with wheat, on the artificial induction of amphidiploidy (that is, of chromosome doubling in hybrids) and the genetics of animals was also considered. The proceedings of the conference have recently been published (*Bull. Acad. Sci. U.R.S.S., Ser. Biol., Nos. 3 and 4. Summaries in English*).

Organic Compounds Toxic to Fruit Pests

Two types of winter wash are necessary for fruit trees. Tar distillates are toxic to the eggs of aphides and apple sucker, but have little effect on those of capsid or red spider. Petroleum oils, on the other hand, are toxic to eggs of red spider and capsids, but not to those of aphides and apple sucker. H. Shaw and W. Steer (*J. Pom. and Hort. Sci., 16, 364; 1939*), in attempting to find a single substance toxic to both these groups, have investigated the ovicidal properties of 44 organic compounds consisting of di-nitrophenols, thiocyanates, naphthalene derivatives and organic bases. As a result of field and laboratory tests on eggs of the vapourer moth (*Orgyia antiqua*), the green apple aphid (*Aphis pomi*), the winter moth (*Operophtera brumata*), red spider (*Oligonychus ulmi*) and apple sucker (*Psyllia mali*), a large proportion of the materials tested was eliminated as showing little promise as winter ovicides. These included all but two of the thiocyanates, the naphthalene derivatives, and the bases other than nicotine and some of the quinoline and iso-quinoline compounds. The materials regarded as worthy of extended trial were 3:5 dinitro-cresol, *n*-dodecyl-thiocyanate (lauryl rhodanate), β -butoxy- β 'thiocyano-diethyl ether and nicotine. All these are suitable for use as supplements for winter petroleum washes. The authors discuss the mechanism of the

toxicity of nicotine in some detail, and favour the view that it penetrates the egg shell and interferes with the development of the embryo.

Soil Decomposition of a Plant Pathogen

SEVERAL fungi which attack plants from the soil disappear when the host is not grown for a certain period. S. D. Garrett, of Rothamsted Experimental Station, has made a study of this action with *Ophiobolus graminis*, the fungus causing 'take-all' disease of wheat (*Ann. App. Biol., 25, No. 4, 742; 1938*). The fungus apparently disappears as a result of natural decomposition by other micro-organisms of the soil. It will remain alive indefinitely in air-dry soil, at low temperatures of 2-3° C., and under sterile conditions. Decay of *Ophiobolus* mycelium is quickest when conditions are such that the normal micro-flora of the soil is greatest. Addition to the soil of energy materials lacking nitrogen, such as glucose or starch, hastens the destruction of mycelium, whilst dried blood, with readily available nitrogen, has the opposite effect. Soil conditions which are least favourable for the parasitism of *O. graminis* may, in fact, best preserve the organism during the non-pathogenic phase.

Proteins and Viruses

PROTEINS which possess the active principle of plant viruses have been isolated by W. M. Stanley and by F. O. Bawden and N. W. Pirie from diseased hosts. Hideo Moriyama and Shunkichi Ôhashi have studied the properties of certain proteins precipitated from healthy plants, and compared them with virus proteins (*J. Shanghai Sci. Inst. (Sect. 4), 4, 17; 1938*). Normal proteins which form minute masses visible under the microscope or ultra-microscope, were obtained without exception from healthy leaves of cucumber, kidney-bean, tomato, poplar, spindle-tree, dandelion, lettuce and egg-plant, and also from petals of bindweed flowers. They were precipitated with acetic acid at a certain hydrogen ion concentration, a method which Moriyama has also used for the isolation of vaccinia virus protein and ϕ phage protein. Some of the protein precipitates exhibited double refraction and all had a low content of nitrogen; they are lipo-proteins. It is suggested, from the general similarity of these preparations with virus proteins, that virus attack disintegrates the protein of the host, appropriates some of the decomposition products for its own formation, and leaves an unbalanced physiology which induces the observed pathological conditions.

Mechanical Properties of *Pinus radiata*

ONE of the exotics which has been most extensively planted in Australia and New Zealand is *Pinus radiata*. It grows comparatively fast and it is therefore not surprising that doubts should have been expressed as to the quality of timber that will result. In a previous pamphlet (No. 81), general information on the timber of the species was given. In the present pamphlet, No. 87 (Melbourne, 1938) "The Mechanical Properties of South Australian Plantation-grown *Pinus radiata*", by Ian Langlands, published by the Council for Scientific and Industrial Research, Australia, the results of the mechanical tests to which the timber has been subjected are given. This little brochure is divided into two parts. The first gives in non-technical language the chief results of

the tests; in the second the detailed results and the methods of analysis are given. The tests show that *Pinus radiata* ranks fairly high among other conifers in so far as its mechanical properties are concerned. A considerable variation in properties according to the position in the tree was found, the sapwood near the butt usually being the strongest portion. The direction of loading relative to the rings did not affect the static strength properties, with the exception of cleavage strength. The impact strength, however, was higher when the load was applied to the tangential surface. Statistical analysis showed that, although there is a correlation between mechanical properties and density, it is not sufficiently high to enable the properties of any particular piece to be estimated from its density. The pamphlet contains a discussion on the influence of rate of growth on the properties of the timber, and also gives a table of permissible working stresses.

The Illinois Basin Earthquake of November 17, 1937

THE Illinois Basin is now considered a seismic district, especially for small shocks. Earthquakes occurred there on January 30, 1907, April 30 and May 1, 1920, March 8, 1923, and November 17, 1937, and this latter has been studied by Ross R. Heinrich and Albert Frank (*Earthq. Notes*, Eastern Sec. Seis., Soc. Amer., 10, No. 3, Dec. 1938). Questionnaire cards were sent out, and, 160 being returned, much macroseismic evidence was available in order to draw a map showing the isoseists on the Wood-Neumann scale. In the centre shocks of intensity V are experienced, rolls of linoleum in the stores being toppled over and canned goods shaken off the shelves. The area covered was approximately 8,000 square miles. This macroseismic data agreed very well with the results obtained by reading the seismograms recorded at various towns. This latter evidence, using Joliet's tables for near earthquakes, gave T , 11h. 4m. 47.7s. C.S.T. and epicentre lat. $38^{\circ} 34' N.$, long. $89^{\circ} 5' W.$, about midway between Centralia and Odin. The epicentre was thus on the north-west limb of the Illinois Basin syncline and on the eastern flank of the Junction City dome. Faults exist near, but not at, the epicentre.

Copper Sulphate Pentahydrate

A SHORT announcement by F. Schacherl and O. Běhounek appeared a few years ago in *NATURE* (138, 406; 1936) describing the preliminary results of their investigation of copper sulphate crystals containing heavy water. These authors have now extended their observations (*Coll. Czechoslovak Chem. Commun.*, 11, 57; 1939). The pentahydrate is greenish in contrast with the blue pentahydrate, and its dissociation, according to the equation

has been studied over the range 20°C. to 60°C. The dissociation pressures of the two deuterates, measured tensimetrically, satisfy the equations

$$\log_{10} p = 11.176 - \frac{3086.98}{T} \quad \text{and}$$

$$\log_{10} p = 10.625 - \frac{2956.88}{T}.$$

The heat of 'hydration' of the pentadeuterate at 25°C. is 6.96 kcal.; that for the pentahydrate is 5.32 kcal., which suggests that D_2O is more firmly bound to the anhydrous salt than water is.

The Ionosphere

IN the issue of the *Journal of Research* of the U.S. Bureau of Standards of December 1938, N. Smith, T. R. Gilliland and S. S. Kirby give a summary of the results deduced from their observations of the heights of the various layers of the ionosphere and the critical frequencies at which reflection from them ceases, during the years 1933-38, in which sunspot frequency has increased. The daily and seasonal changes were regular over this period. The E layer had a minimum height of 110-120 kilometres, and its critical frequency varied as the fourth root of the zenith distance of the sun and as the intensity of solar radiation. At night the F layer had a minimum height of 300 kilometres; in the daytime it descended to 225 kilometres and in the summer had a second member at 350-400 kilometres. The critical frequencies for these layers were much higher than for the E layer and less regular. The long-period variations of critical frequencies for all the layers followed closely the variations of sunspot numbers. While the latter increased from 5 to 120, the critical frequencies increased for E by 25 per cent and for F by about 100 per cent, corresponding to increases of ionization of 55 per cent and 300 per cent respectively.

Total Solar Eclipse of June 8, 1937

O. B. MICHIE has recently published a report of the New Zealand Total Solar Eclipse Expedition to Canton Island on June 8, 1937 (*Mon. Not. Roy. Astro. Soc.*, 99, 2; 1938), in which he gives a brief description of some of the results obtained, more especially with the 19-ft. coronagraph and the 78-in. camera. It is interesting to notice that the two instruments gave very different results. The coronagraph showed a wonderful wealth of detail throughout the inner corona, and, in addition, the prominences were well defined. Nevertheless a 45-second exposure failed to reveal the corona beyond 1.5 diameters from the limb of the sun. By using the 78-in. camera it was possible in some cases to follow the streamers to distances of 3.5 or more diameters. The camera was provided with a rotating sector to enable photographs to be taken with the object of studying detail over a wide range of light intensity. The photographs obtained in this way and also the short exposure plates taken with the coronagraph showed several dark regions in the corona extending inwards to the rim of the eclipsed sun. From these and other details there is the suggestion of electromagnetic fields in action.

Radiants of the Orionid Meteor Shower

J. P. M. PRENTICE, director of the Meteor Section of the British Astronomical Association, has recently issued a paper with the above title (*J. Brit. Astro. Assoc.*, 46, 4; 1939) in which he gives an account of his work on the Orionids in 1936 and 1938. In previous papers he suggested that there is a 'radiant pattern' for this stream, and that the various centres of radiation are not stationary, as Denning believed. There was the further suggestion that each stream, as it moved eastward, came to a maximum on the same meridian of right ascension at about $\alpha = 96^{\circ}$. The paper gives very full details of the work which was carried out to investigate the last result, and Prentice is convinced that the Orionid streams have a standard meridian of maximum at $\alpha = 96^{\circ}$. This result is very interesting, but there seems to be no physical explanation for it.

The Indian Science Congress Association

Lahore Meeting

THE twenty-sixth meeting of the Indian Science Congress Association was held in Lahore in January, this being the third occasion upon which the Congress has met in the capital of the Punjab.

The president of the Association, Prof. J. C. Ghosh, professor of chemistry in the University of Dacca, devoted the first part of his address to a survey of the development in India of chemical research during the last decade. He showed that the appeal made by Prof. J. L. Simonsen in 1928 for a more intensive study of India's rich natural resources has met with a gratifying response, and, whilst deploring the lack of interest in inorganic chemistry, he was able to point to the valuable contributions made to physical chemistry. He directed particular attention to Prof. Bhatnagar's outstanding work in magneto-chemistry, to Prof. J. N. Mukherjee's elaborate investigations on the colloid chemical behaviour of soil constituents, and to the work of his own laboratory on the interplay of matter and radiation.

The second part of his address was an appeal for the formation in India of an All India Council of Scientific and Industrial Research. Research in agriculture has received generous support from public funds, but little or no attempt has been made to implement the recommendations of the Holland Industrial Commission. He suggested that there is little prospect of the schemes for industrial development, advocated at a recent conference of the Provincial Directors of Industry, meeting with success unless this development is supported by well-equipped and adequately staffed research organizations.

THE EARTH'S MAGNETISM AND THE UPPER ATMOSPHERE

The presidential address given by Dr. K. R. Ramanathan to the Section of Mathematics and Physics was devoted to geomagnetism; it was an extremely interesting, well-balanced and up-to-date survey of this subject, which after many decades of relative neglect has again begun to attract the attention of physicists. Apart from the standing challenge to theoretical physicists which is offered by the problem of the existence of the main magnetic field of the earth (and also of its secular variation), the subject has come into new prominence through its bearing on radio physics (the properties of the ionosphere) and on the entry of cosmic rays into the earth's atmosphere. Solar physicists are also concerned with the subject, because the time-pattern of geomagnetic disturbance, undoubtedly due to the sun, differs materially from that of the main changes hitherto observed on the sun's surface, and indicates that solar changes of much terrestrial significance are not yet properly distinguished by solar observers.

Dr. Ramanathan's address was mainly devoted to the transient changes of the earth's field, which are associated with the sun and the ionosphere, but he also dealt briefly, at the outset, with the main field, in connexion with which he made some interesting

quotations from the great memoir by Gauss on the spherical harmonic analysis of this field. In his survey of the transient variations, Dr. Ramanathan described the solar and lunar daily magnetic variations, magnetic storms, and—what is the most recently established type—the brief disturbances affecting only the day hemisphere, associated with radio fade-outs and solar eruptions. He rightly directed attention to the important contributions to geomagnetic science that have come from India, namely, the important work of Broun on the lunar daily magnetic variation, based on the data obtained at the Trivandrum magnetic observatory maintained for many years by the Maharajah of Travancore, and the truly monumental discussion of the Bombay magnetic data, by Moos. In recent years new Indian contributions to ionospheric studies have come from Profs. M. N. Saha and S. K. Mitra and their students.

In his survey of geomagnetic problems, Dr. Ramanathan provided an admirable brief outline of the present state of knowledge in this field, which should be of value to physicists everywhere who desire an introduction to the subject.

ANALOGY AMONG CHEMICAL ELEMENTS AND RADICALS

The first part of the presidential address to the Section of Chemistry, by Prof. P. B. Sarkar, included an account of the volumes and magnetic properties of ions and the relation between these properties and colour with the electronic structures of the rare earth ions. The effect of deformability was considered in its relation to isomorphism, where the influence of ionic radii was fully explained.

In this part of the address special emphasis was laid on the modern explanation of cases of isomorphism which cannot easily be understood or explained on the older views. As an example, it is stated that the ionic radii of Sr^{2+} and Be^{2+} are both 0.34 Å. The only difference between the two ions is in their polarizing power. A series of isomorphous simple and double sulphates and corresponding fluoberyllates have been prepared by Ray, and in almost all cases the fluoberyllates resemble the corresponding sulphates in both physical and chemical properties. The X-ray spectrum of barium fluoberyllate is practically indistinguishable from that of barium sulphate.

Although pure alkali aluminium fluoberyllates corresponding with alums have not been prepared, mixed crystals of alums containing both sulphates and fluoberyllates have been obtained. Prof. Sarkar directed attention to the analogy between the monofluophosphate ion PO_3F^- and the sulphate ion SO_4^{2-} . Several simple and double monofluophosphates as well as compounds of the alum type isomorphous with the corresponding sulphates have been prepared in his laboratory. Another case of isomorphism supported by mixed crystal formation is afforded by the formates and nitrites studied by Ray.

Prof. Sarkar concludes that three essential factors determining chemical similarity are (i) equality of ionic charge or valency, (ii) similarity of structure, and (iii) approximate equality of ionic radii. Of

these the first is the most important and demands complete equality, whereas the other two permit of slight deviation within a narrow range.

CONSERVATION OF INDIA'S MINERAL WEALTH

Dr. S. K. Roy, in his presidential address to the Section of Geology, chose as his theme the conservation of India's mineral wealth. Considering the vast size of the country, mineral occurrences are few and far between, and for this reason alone they should be stringently conserved to meet the growing demands of industry and national defence. India possesses deposits of both coal and petroleum, and attention should be directed towards their conservation.

Owing to the number of serious accidents which have occurred during recent years, researches on safety in mines have taken precedence over fuel research. Hydraulic packing, known as sand-stowing, has been found by the Coal Mining Committee to be an efficient method of preventing practically all major disasters, and there is no reason, therefore, why this should not be put into practice by law and the energies of experts now turned towards fuel research. There is ample scope for this, particularly in the Jharia coalfield, where about 30 million gallons of tar are wasted annually in production of soft coke. Of the 300 million gallons of petroleum consumed annually, only 76 millions are produced in India, and yet little is done to conserve the limited supply available.

Apart from coal and oil, there are a great many minerals which should be conserved. India is by far the largest producer of mica and could well command the world market were the industry efficiently organized. As things are, the mica deposits are for the most part exploited by unscrupulous small capitalists anxious only to fill their own pockets. Once they have recovered such mica as is easily available at the surface, they abandon the deposits. Thus in course of time valuable underground resources become overgrown and no one is aware of their existence. Another source of loss to the mineral wealth of India is the exceedingly low price at which minerals such as kyanite, magnesite, manganese, beryl, etc., are exported, simply because there is little demand for them within the country itself.

The history of India shows that years ago metals such as gold, silver and copper were available in large quantities. Diamonds also occur at three different geological horizons, and until the middle of the last century India supplied 98 per cent of the world's output. At the present time, however, diamond mining is extinct.

India cannot afford to ignore this wealth, which with the help of properly trained geologists, mining engineers and chemists, backed by local government departments, could be exploited to the advantage of the nation as a whole.

THE GEOGRAPHICAL PERSONALITY OF INDIA

The presidential address by Mr. N. Subrahmanyam to the Section of Geography and Geodesy covered widely, if superficially, almost every aspect of the life of India in an attempt to assess the present characteristics and the direction of change of Indian civilization to-day.

A review of physical factors, including climate and its effect on production, was comprised under the

heading of static geography. Then followed under the heading of dynamic geography an account of the more modern influences that are permeating India and an estimate of their effect. India has long been awakening into modernity through impact with Europe, and particularly through British permeation. Her isolation has gone: new forces permeate cities and towns and through the motor-car and radio are reaching the villages, where eighty per cent of the inhabitants dwell. Self-sufficiency is rudely shaken: even caste is adapting itself to new conditions. The old conditions and obstacles to progress such as pressure on the land, recurrent famines and appalling poverty are no longer accepted; their courses are recognized to be removable.

In short, man in India has fallen behind, but now he is catching up and bids fair to take full advantage of his opportunities. A new composite civilization should emerge as a synthesis of Eastern and Western cultures. From the medieval India there is emerging, though naturally not without discord in places, a modern India.

INDIAN FOREST MYCOLOGY

Dr. K. D. Bagehee's presidential address to the Section of Botany dealt with Indian forest mycology with special reference to forest pathology. It was in the early years of this century that Dr. E. J. Butler, at the time mycologist to the Agricultural Research Institute at Pusa inaugurated by Lord Curzon when Viceroy of India, wrote a paper or two on Indian forest fungi published in the *Indian Forester*. The subject, then almost a sealed book, has remained so until within the last few years. Dr. Bagehee's address shows that considerable progress is being made in a fascinating branch of forest studies, and one which will become of increasing importance in the years to come.

Dr. Bagehee stated that most of the forest diseases of India, including heart-rot, are indigenous. They seldom become epidemic, the organisms causing them being more or less in a biological balance with their hosts. When this balance is disturbed by unusual weather conditions or other factors, an indigenous disease temporarily becomes epidemic; when the disturbance ends, the disease resumes its former status, effecting cumulative damage through slow and constant action. But parasites coming into a new region often find some species particularly susceptible to their attack, because of the lack of any established balance between the parasite and the host, and thus an epidemic breaks out.

It may be pointed out that the balance mentioned above under which the primeval forest has maintained itself through the ages may be, and often is, interfered with by good forest management, the sylviculturist endeavouring to eliminate Nature's exuberant abundance in the production of material of little economic use and to increase the volume of the crop per unit of area whilst keeping it clear of dead and dying material. Whilst on one hand this should reduce the danger from insect or fungus pests, in epidemics the reverse may be the case. In plantations of one species, especially exotics, the forester has already realized the position.

Dr. Bagehee divided his subject into six main heads: (1) Coniferous rusts affecting conifers in the mountains; (2) root-and-stem-rotting fungi killing conifers in the mountains and hardwoods in the plains; (3) canker pathogens infesting native and

some introduced hardwood species; (4) nursery diseases; (5) timber diseases—timber-rotting fungi; (6) ecology and habits of the forest fungi of the forest floor or on the woody undergrowth or sub-aerial parts of the trees.

Dr. Bagchee discussed in some detail the diseases which he has studied, and dealt with certain possibilities of control measures. The address is a valuable contribution to the available knowledge on this subject.

BATRACHIANS AND THEIR ENVIRONMENT

The president of the Section of Zoology, Prof. C. R. Narayan Rao, directed attention in his address to changes induced in closely related frogs and toads by different influences of environment. The observations are of special interest because they are due to the author's own studies in an area of highly diverse physiographical conditions, and because they illustrate the possibilities that lie in ecological work of this kind. To select one or two of his points. We are accustomed to think of batrachians as limited to regions of great humidity, but some live continuously in "conditions of extreme dryness". These show distinctive adaptations: some inhabit deep burrows except during a short humid period; in *Uperodon* the skin is developed to absorb and retain water, which may thus be available during drought. Aquatic batrachians have large kidneys; those attuned to dry conditions possess relatively small kidneys, a correspondingly large bladder and a surprisingly small amount of excretory products in the urine. Lastly, the aquatic forms reduce the exposed area of moist skin by resting flat upon the ground, whereas the others sit with a half-perpendicular pose.

Another striking correlation, suggested tentatively by Prof. Narayan Rao, is that between the presence or absence of the tympanum and the temperature of the air or water in which the batrachians live, for he finds that higher temperature leads to conspicuous development of the tympanum, lower temperature to its reduction or absence. Temperature seems also to rule the shape of the body, cold temperatures inducing rather globular forms with reduction of surface area; whereas high temperatures are associated with extensive surfaces, and with the habit of aestivation, which sets in at 105° F.

Frogs typical of dense areas of jungle have elongated bodies and shortened hind limbs. Species represented both in forest and on high ground lay fewer eggs in hill streams and pools and, correlated with the smaller ovary, the fat-body also undergoes reduction. The studies made by Prof. Narayan Rao in South India offer many suggestions which workers in other parts of the world will be anxious to test upon their own amphibian population.

TRIBAL CULTURE CONTACTS AND ACCULTURATION

In India there are nearly thirty million primitive peoples, among whom tribal society in many areas is experiencing depopulation through changes in economic and social life. In certain groups, however, which have not lost their vitality and interest in life, cultural contacts bring about the selective adoption of alien traits, a cultural symbiosis or acculturation. This topic formed the subject of Dr. D. N. Majumdar's presidential address to the Section of Anthropology.

Nowhere in India is this cultural symbiosis or acculturation more patent than in Bastar, an

important feudatory State of the Central Provinces. Here the native population is Gond. Foreigners and immigrants, claiming Kahatriya origin, are believed to have mixed freely with the native population. Two groups, having social precedence, claim Kahatriya origin; the remaining groups are regarded as of indigenous origin, probably with good reason. The linguistic and ethnic frontiers in Bastar are very uncertain; and it has for long been a melting-pot of races and groups. The infiltration into an aboriginal area of caste peoples, who dominate the native population, has resulted in an interdependence of the two groups. The *Kabadi* custom is an example of this interdependence and co-operation. According to this custom, when a member of one of the inferior groups is in urgent need of money, for example, for the payment of a fine, or to meet the expense of a ceremonial wedding, he will borrow from the master for whom he works, repaying by agricultural service. Formerly, when tribal organization was strong, if such a sum of money was required, it was raised by group effort. Now that tribal and group solidarity is dissipated; the economic helplessness of the inferior groups is exploited by the caste people, the loans often entailing lifelong servitude, which may pass to his heir, if a man dies while still in debt.

Nevertheless, in some areas economic interdependence has led to a healthy reciprocity in cultural life, as, for example, in the Dusseerah religious festival, which has brought together the various cultural groups of Bastar as participants in a great cultural heritage. Further, many indigenous institutions survive to serve a useful purpose. Such, for example, is the dormitory institution, where unmarried youths and girls collect to dance and sing together at night. Originally, under tribal organization, this institution was intended to enable the warriors to lie in readiness to protect the women and property of the group from raids. It now serves as an educational institution, in which the young people learn the group standard of social life, discipline, the economic pursuits characteristic of the group, social and ceremonial duties relating to sex and associated matters. Thus the dormitory now fulfils an important role in the tribal life of the community.

INSECTS AND THEIR ROLE IN INDIAN AGRICULTURE

Under this title Dr. T. V. Ramakrishna Ayyar contributed an interesting presidential address to the Section of Agriculture. The substance of his discourse was a general survey of insects in relation to man and, in particular, in connexion with problems of Indian agriculture.

After discussing estimates of losses due to insect depredations in the United States, Dr. Ayyar compares similar losses in India. In so far as rice, wheat, cotton, sugarcane and oil-seed are concerned, he computes the annual losses of these crops, alone, at more than 200 million rupees. While the insect pest problems of the different areas of India differ considerably in geographical, climatic and other conditions, and according to the crops grown in each region, there are a few species of so wide a range as to affect India as a whole. Of these latter, locusts are of primary importance, and especially noteworthy was the large-scale infestation of the desert locust (*Schistocerca gregaria*) during 1926-31.

After reviewing various artificial methods of insect

control, the subject of natural or biological control was then considered. In South India, biological control has so far been tried on an organized scale against two species of insect pests. One, the fluted scale (*Icerya*), which was introduced into the Nilgiris about 1927-28, has been considerably checked but not completely exterminated by the beetle *Novius cardinalis*. The other pest, the coco-nut caterpillar (*Nephantis serinopa*), is indigenous and has a complex association of various insects living in relation to it. A biomimetic study of this association has been attempted, and some of the parasites have been found occasionally to exercise appreciable control over this caterpillar. In so far as pest plants are concerned, the cochineal (*Dactylopius*) has brought about a remarkable and spectacular result in the eradication of prickly pear.

In dealing with the organization of entomological work, Dr. Ayyar rightly stressed the importance of taxonomy and aptly remarked that discrimination between species is the starting-point of the majority of Indian biological problems. Other important aspects emphasized by him are the need for studies of ecology and of bioclimatics. He remarked that while pure science is often immensely practical and applied science is often very pure, between the two there is really no dividing line, both being necessary for the intellectual and material needs of man. In conclusion, he pleaded for the giving of greater encouragement in scientific institutions and universities to applied science, which is necessary to meet the many material needs of India.

PHYSIOLOGICAL RESEARCH IN INDIA

In his presidential address to the Section of Physiology, Prof. N. M. Basu made a plea for the establishment of physiological teaching and research in India, by the provision of better facilities for the holders of teaching posts, and the modification of existing degree courses to encourage the development of the student along the right lines. In spite of the many obstacles, much fruitful work has been carried out in India in recent times. The normal blood picture of the Indian has been established in many districts, and an extension of such work to other areas would be of the greatest value to the practitioner of medicine, as would an extension of the work on the standards of vital capacity and their relation to surface area and height.

Much time has been devoted to nutritional surveys and the investigation of the diets of various areas, and of the effect of supplementing those diets which were found to be deficient. Dietary surveys made in South Indian villages showed that not only are deficiency diseases common, but also the actual calorie intake is lower than the minimum. Addition of very small amounts of milk to such diets is very beneficial, chiefly through the calcium content of the supplement. The diet of middle-class Bengalee families has been found to be deficient in animal fat, animal protein and in calcium.

A considerable amount of work has been devoted to analyses of the composition of various foodstuffs, and to the determination of the biological values of the proteins of common Indian foods. Rice has a high biological value, and, together with pulses, forms a valuable addition to a diet. The vitamins have, naturally, attracted many workers. Vitamin C has been found to exist in large quantities in such

native fruits as litchi, mango and guava, and the importance of this vitamin in aiding resistance to infection has been established. The occurrence and stability of carotene and vitamin A in indigenous plants has received attention, and observations of interest have been made on the effect of diet on the absorption of this vitamin from the alimentary tract. An inquiry into the requirements and saturation of various groups in vitamins C and B₁ is now in progress, and promises to yield interesting results.

The preponderance of nutritional research is due to the fact that ample funds are available for it. If they were as well supported, other branches of physiology would advance as rapidly, and the subject would be able to take its full role in the development of biological science and medicine in India.

DYNAMIC STRUCTURE OF HUMAN PERSONALITY

In his presidential address to the Section of Psychology, H. P. Maiti pointed out that personality in its practical aspects meets us to-day wherever we have to deal with human nature, whether in hospitals, in clinics, in schools and colleges, or in industrial organizations.

There has always been a popular interest in personality, but until recently scientific psychology avoided it, probably because of its complexity. The work of the psychiatrists towards the end of the last century familiarized us with some of the problems of the abnormal personality, and Janet distinguished two main types of personality structure, namely, the 'psychasthenic' and the 'hysteric'. For psychiatric practice this work was fruitful, but it threw little light on the mechanism of personality integration. Nor in spite of the enormous amount of work devoted to their study have personality tests proved of reliable validity, probably because, if personality is a functional whole with interacting parts of which some are dominant over others, then no test or description can be adequate unless it can show the role of each part in the work of the whole. We need a dynamic theory of personality.

The most likely fields of study are (a) the clinical and psycho-analytic fields, where variations of function through pathological deviations can be observed, and (b) through observation of the normal changes attendant upon development.

The recent modification of the Freudian theory of the neuroses throws some light on a number of difficulties. The distinction of the Id, Ego, and Super-ego, roughly equivalent to the more popular distinction between passion, reason and conscience, shows the effect of the social influences of the early years on the rest of the personality. Genetically, the three are continuous one with the other, and can only be considered separate for functional purposes. The Id is undifferentiated instinct not yet organized under the unity of the Ego; the Ego gradually develops as the Id comes into contact with reality, and the Super-ego grows later out of the developing qualities of the Ego, thus helping the Ego to keep the Id in check.

These factors in their mutual interaction constitute the fundamental scheme of personality in an individual, and form a continuously active system, each part being in dynamic interaction with the other two. In the healthy mind the three structures harmonize, and retain their plasticity throughout life.

Science News a Century Ago

Pentland's Travels in Peru and Bolivia

At a meeting of the Royal Geographical Society on March 25, 1839, extracts were read from a paper by Dr. Bowring "On the Geography of the Country around Cuzco", and an account was given by Joseph Barclay Pentland (1797-1878), H.M. Consul-General in Bolivia, of his travels in Bolivia and Peru during the preceding two years. With the exception of General Miller, it was believed Dr. Bowring and Pentland were the only persons who had visited Cuzco with a scientific object. During his stay in the city—the ancient capital of the Incas—Pentland made plans of the ancient and modern city, and examined the remains of Peruvian architecture. In his paper, he dwelt upon the extraordinary style of cyclopean construction of the ancient Peruvians, which was no less remarkable for the care shown and the remarkable size of the stones, some of which exceeded 150 tons in weight. In the course of his journey, he determined by astronomical observation the position of nearly forty places and he determined their height by barometric measurements. He also referred to a canal cut across a pass of the Western Cordillera into the valley of the Tacna. This was planned by an Englishman named Scott and undertaken chiefly by British merchants. At one point it was 14,652 ft. above sea-level.

A Sawing Machine for Iron Rails

On March 26, 1839, Joseph Glynn, F.R.S. (1799-1863), described to the Institution of Civil Engineers a "Sawing Machine for Cutting off Railway Bars", which had been erected at the Butterley Iron Works, Derbyshire, for cutting rails for the Midland Counties Railway. The machine had two circular saws each of them being 3 ft. in diameter and $\frac{1}{4}$ in. thick. They were mounted in headstocks which could be moved at right angles to the rails. They revolved at 1000 revolutions per minute between two disks of cast-iron faced with copper, and dipped into water. The rails were sawn while hot, it taking 12 seconds to saw through the ends of a 78 lb. rail.

Audouin's Advice to a Naturalist

A FRENCH naval officer, M. Lefebvre, about to travel in countries bordering the Red Sea, solicited instructions as to what objects he should study. Among those he appealed to was the French entomologist Jean Victor Audouin (1797-1841). In the *Athenaeum* of March 30, 1839, appeared extracts from Audouin's remarks. "The Gulf of Suez", the article said, "is extremely rich in molluscs, zoophytes, crustaceans and annelids and it is very desirable that the fugitive colours of the Doris, Bursatella, Orchidia, and Tritonia, etc., should be delineated. The animals of several of the shells, also found in the Red Sea, are hitherto unknown; for instance the *Anatola*, and the same may be said of the zoophytes, concerning which it would be highly important to possess the particulars of form as well as colour, both of which alter so quickly; those of the polypi with flexible stems would be particularly interesting. . . . It is supposed that many new spiders may be found in Abyssinia, and the genus *Lycoea*, to which the *Tarantula* belongs, should be especially examined. It is, however, chiefly the class of insects which may be enriched by a journey to Abyssinia."

Societies and Academies

Paris

Academy of Sciences (C.R., 208, 545-608, Feb. 20, 1939).

H. COLIN and Mlle. M.-M. CHOULET: Formation of inulin in annual plants. Conditions for formation of inulin are more easily realized in the Campanulaceae than in the Compositae.

G. MALHOTRA: Correlations between related individuals, in the hypothesis of homogeneity.

V. A. KOSTITZIN: Compatibility of stable singular points of differential equations.

H. CARTAN and S. MANDELBOYT: Solutions of Carleman's problem for a finite interval.

D. BÉLOREZKY: Imaginary triple collisions in the plane problem of three bodies.

R. JAMIN: Theorem relating to the isentropic flow of perfect gases.

J. BETHENOD: Determination of the range in which an alternating current are functions.

F. CARBONAY: Propagation of high-frequency oscillations on networks for the transport of electrical energy.

T. KOFMAN: Action of visible and ultra-violet light on periodic reactions.

G. REBOUL and E. THIBAUD: Emission of ionizing radiations by salts of ordinary metals.

J. SOLOMON: Splitting of radioactive nuclei by neutrons. It is suggested that the action is analogous to 'predissociation' of molecules.

H. VON HALBAN, JUN., L. KOWARSKI and M. MAGAT: Intensity of the neutrons in cosmic radiation. Radio-element ^{86}Br was produced by cosmic ray neutrons, the intensity of which was much greater at a height of 9,500 metres in an aeroplane than on the ground in Paris.

Mlle. T. GUILLMART: Absorption in the ultra-violet of oximes in the solid state. The bodies exist in two forms with different spectra.

Y. DOUGET: Principles of cryoscopy and the construction of a cryoscopic apparatus.

C. DUVAL and G. MAKARS: Micro-estimation of halogen ions; acid-alkali test.

G. WETZBOFF: Reaction with chlorine of some derivatives of the phosphonitrile radical.

Mlle. M. MURGIER: Preparation of soluble molybdic acid.

Mlle. Z. SOUBAREW-CHATELAIN: Constitution of molybdic acid in dilute aqueous solution.

R. PAUL: Opening of hydrofuranic and hydro-pyranic cycles by acetic anhydride.

W. S. REICH: A new series of esters of the oces, the asoyl-esters.

J. LUGNON: Instantaneous determination, without calculation, of any altitude of a radio-sonde.

P. GAVAUDAN, Mlle. N. GAVAUDAN and J.-F. DURAND: Effect of some hydrocarbons and their derivatives on mitosis and on cytodiarrhesis.

A. TOURNADE and G. CHARDON: Mechanism of post-depressive hypertension observed after temporary insufflation of the lungs.

G. UNGAR and J.-L. PARROT: Influence of bleeding on the power of the plasma to destroy histamin.

H. MUNTZ: Fundamental laws of haemodynamics.

Mlle. V. DEUTSCH: Sedimentation constant and molecular weight of syphilitic reagent.

S. METALNIKOV, A. YAKIMACH and O. YADOFF: Action of radioactive radiations on microbes.

Dublin

Royal Irish Academy, Feb. 27.

J. M. O'CONNOR: The significance of monomolecular layers of fatty acids in the control of animal oxidation. The influence of temperature from 0° C. upwards on the oxygen consumption of the frog was examined. It is found to show sharp increases between 6° and 14° and between 21° and 30° and at 18°. These changes correspond in position and in extent to the expansion of a monomolecular layer of myristic and palmitic acid in the proportions in which they occur in the frog, and to the melting of palmitic acid.

A. AUSTIN MILLER: River development in South Ireland. The rivers of South Ireland originated as south-flowing consequent streams on a plane above the summits of the present mountains. Later, the rivers have, by repeated captures, extended along the east-west synclines of soft carboniferous rocks until many of them flow in this direction from source almost to mouth, turning south only in the last few miles of tidal estuary. For some time the sea-level stood 800 ft. above that of to-day and cut a broad beach, backed by a line of cliffs, at that height on the southern slopes of the Knockmealdowns and other mountain groups. The sea-level declined by stages to 400 ft., then to 200 ft., then to the level of the pre-glacial raised beach a few feet above Ordnance datum, then to about 100 ft. below present sea-level, returning only quite recently to the present position, drowning the estuaries.

Vienna

Academy of Sciences, January 12.

W. J. MÜLLER, E. LÖW and F. STEIGER: Difference in the rate of corrosion of pure and commercial aluminium in alkaline solutions. The E.M.F. of the local voltaic couples causing the corrosion is the same for both kinds of aluminium; the higher velocity of corrosion of commercial aluminium is due to the lower resistance of the surface film, brought about probably by the inclusion of metallic impurities.

J. LINDNER and B. ZAUNBAUER: Synthesis of quinoline by tetraethylamines. 7,8-tetramethylenequinoline.

J. LINDNER, F. SCHMITT and B. ZAUNBAUER: Hydrindene derivatives (2). Simple substitution products.

A. SKRABAL: Continuity of the kinetics of bleaching solution. The various kinetics of bleaching solution are all derived from a single law involving two velocity coefficients.

J. KISSER: Frequency of abnormalities of the leaves of *Juglans regia* due to a late frost.

January 19.

M. STARK: Stages in the development of crystalline schists of the Radstädter chalk beds in the Ahrtal and Gasteintal.

M. TOPPERGER: Theory of earthquake disturbances. The motion of the ground is assumed to be of the form $x = A e^{i\omega t} \sin \omega t$.

O. PAULEHN: Studies of the Raman effect (97). Poly-substituted benzols.

J. BRUNNER: New find of Hippurion fauna at Veles in Macedonia.

A. ERDELYI: Series involving products of Laguerre polynomials.

Washington, D.C.

National Academy of Sciences (Proc., 25, 1-54, Jan. 15, 1939).

W. J. ROBBINS and MARY B. SCHMIDT: Vitamin B₆, a growth substance for excised tomato roots. Slow growth has been maintained over a period of more than two years in a solution of mineral salts, pure cane sugar and thiamin. Growth is improved by substituting a light brown sugar for the pure cane sugar, due apparently to presence of vitamin B₆. Probably the roots synthesize sufficient vitamin B₆ for slow growth in solutions containing thiamin.

W. J. V. OSTERHOUT and S. E. HILL: Chemical restoration in *Nitella* (3). Effects of inorganic salts. Irritability disappeared after two to six days in distilled water but can be restored by 0.01 M. sodium chloride or sulphate in five minutes. This is considerably longer than is required with organic salts, suggesting a different mechanism.

E. DERSHEM: Photomicrographs of thin bone sections by the use of fluorescent X-radiation. A radiator containing an element the K emission lines of which are a little shorter in wave-length than the K absorption wave-length of the principal element of the specimen is used. This radiator (scandium oxide for photomicrographs of bone) is irradiated with an ordinary X-ray tube, and emits radiation heavily absorbed by the specimen. The 'camera' must be evacuated.

G. D. SNELL: Induction by irradiation with neutrons of hereditary changes in mice. Both X-rays and neutrons produce translocations and sterile F₁ males, but both fail to produce detectable numbers of recessive mutations.

D. BODENSTEIN: Imaginal differentiation inaugurated by oxygen in *Drosophila* pupae. The presence of oxygen, rather than a differentiation hormone in the anterior part, seems to be necessary for differentiation of the abdominal ectoderm.

H. C. SHERMAN, H. L. CAMPBELL and C. S. LANFORD: Experiments on the relation of nutrition to the composition of the body and the length of life. Contrary to the classical view that the chemical composition of an organism is rigidly specific, it is found that rate of calcification in the normally developing body can be varied by adjusting calcium intake within the normal range, without departure from full health. The higher intake seems to be permanently advantageous. High intake of vitamin A has improved length of life and vitality of offspring.

E. B. WILSON and JANE WORCESTER: Resolution of tests into two general factors.

W. R. MILES: Steady polarity potential of the human eye. Electrodes are placed on the skin near the eyes and the body potential balanced out. The potential of the eyeball is closely proportional to the sine of the angle of rotation of the eye.

O. STRUVE: Physical state of the interstellar gas clouds. A theoretical discussion leads to the view that there is a high abundance of hydrogen atoms in interstellar gas; roughly, hydrogen atoms to calcium atoms are as 10⁶ to 1.

G. A. MILLER: Groups of degree n in which the largest degree of a substitution is a minimum.

E. T. BULL: Euler's concordant forms.

S. LURSCHEITZ: Mapping of abstract spaces on polytopes.

J. W. TUCKER: Intrinsic metric of a polytope.

J. W. ALEXANDER: Concept of a topological space.

Forthcoming Events

CHEMICAL SOCIETY, March 29-31.—Anniversary Meetings. March 29, at 6.—Sir Henry Tizard, F.R.S. Rutherford Memorial Lecture to be delivered at the Royal Institution.

March 30, at 2.30.—Annual General Meeting. At 4.—Presidential Address.

BRITISH PSYCHOLOGICAL SOCIETY, March 30-April 3.—Extended General Meeting to be held at Reading.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned

SCIENTIFIC OFFICER (Physicist) to the Wool Industries Research Association—The Secretary, Torrington, Huddersley, Leeds, 6 (April 1).
DEMONSTRATOR IN INORGANIC AND PHYSICAL CHEMISTRY in Bedford College, Regent's Park, N.W.1—The Secretary (April 6).

INSPECTOR OF AVIATION FUELS AND LUBRICANTS in the Aeronautical Inspection Directorate—The Under-Secretary of State, Air Ministry (8.2.4), Berkeley House, W.1.

LECTURER (WOMAN) IN GEOGRAPHY in the Lincoln Diocesan Training College—The Principal.

Polar Exploration

THE most casual reader of the daily press will have noticed an increased frequency of references to expeditions, mostly to the Arctic, in recent years. Speaking broadly, before the Great War, interest in Great Britain in the Arctic was limited mainly to hunting parties and to one or two scientific expeditions led by senior men. Since the War, however, there have been some thirty or forty summer expeditions and half a dozen wintering expeditions in the north from this country, excluding many smaller ventures of two or three men in a party. More significant still, these have practically all been organized and manned by young men, usually from a university.

We are not concerned here with the reasons for this remarkable change, and indeed no one reason will account for it. It is important to realize, however, that it is not just a fashion or a cult, nor can it be dismissed lightly as an outlet for the energy of youth. Not only do the expeditions take themselves quite seriously, but they nearly always attempt serious work and usually return with useful and important results. Youth has certainly won its spurs in the field of polar exploration.

Now, as before the War, the real spiritual parent and patron of all exploration from Great Britain is the Royal Geographical Society; but in consequence of this new activity there has arisen a group of subsidiaries, in close and harmonious touch with the Society, who make it their business to foster and even direct such work.

Perhaps the most official and permanent of these is the Scott Polar Research Institute at Cambridge, established in memory of Captain Scott. While its slender funds still limit its assistance to matters of advice on equipment and access to past records, it is rapidly becoming a centre at which experience

can and does gather. Moreover, its half-yearly publication, the *Polar Record*, does an important service in recording and reviewing the work done in the field, by all nationalities and in both the polar regions. The Oxford University Exploration Club is another organization which has for many years produced at least one expedition a year, and has seen to its results being published. It does not confine its activities to the polar regions. The more junior but numerically larger Public Schoolboys Exploration Society is yet another, with aims somewhat similar to those of the senior organizations. Worthy of mention also, though not as directly fostering exploration, are the Antarctic Club, formed in 1924, and the Arctic Club, formed in 1932. These are social clubs only, and their functions serve as happy reunions of a private character.

The real backbone of financial support comes from none of these, however, for their resources are very limited, but from an innumerable and unnameable series of sources which have no publicity nor do they seek it. These are learned societies, colleges and institutions, and travel funds, as well as private individuals who come forward with grants so that the expense to the actual members of an expedition shall not be prohibitive.

There has been a small measure of criticism of this somewhat fortuitous method of financing expeditions. It is urged that there would be more efficiency and less wastage if there were some general fund. It is pointed out that expeditions and even parent organizations are liable to become rivals for private favours and public subscriptions.

There are two answers to these criticisms. In the first place, the freedom in the present

arrangement, whereby anyone with a keen desire to explore can find ways and means to do so, is not to be lightly given up. A regimenting of such desire would often strangle it at birth. Secondly, the reason for the support now available is almost always personal. A college or a parent or a travel fund rarely thinks of the abstract cause of exploration or science when it makes a grant; it is considering only the training or the reward of a likely individual. Much of the money now sending young men to live arduously in the polar regions would never be available as a subscription to a General Exploration Fund, however fine its aims or dignified its management. That there is need of a fund of another character will be shown later, but there is no overwhelming case for a general exploration fund for the provision of these junior expeditions.

Next in the list of current criticisms comes the remark sometimes heard that the scientific work is not of a very high order. It is quite true that the range and depth of scientific work on, say, the H. G. Watkins' Expedition to Greenland, was not comparable with that of the Wegener Expedition, there at the same time. This was partly due to a difference of aim and of resources, but mainly of selection, the Germans being established scientific workers of experience and maturity, the Englishmen being beginners or amateurs; in one the object was avowedly scientific, in the other exploration was the chief aim.

Incidentally, it has been suggested in some quarters that in polar exploration science is made the cloak for adventure. This is undoubtedly true to some extent, and some leaders have even been hypocritical about their aims in this respect, in order to get support. Such practices would, of course, defeat their own object in the end; but since it usually means that the scientific workers they do take are doubly keen, one can scarcely say that serious harm is done. In any event, it is open to question whether love of travel can really be divorced from any field-science, and if we elect to regard travel-eagerness as something trifling or unworthy, then we shall have to include Darwin and Wallace in our criticism.

Granting that some of the scientific work done is low in value—inevitable when juniors form so large a proportion of the workers—can we say we are satisfied with the organization of the work and the use made of it?

This is probably the weakest point in the present type of expedition, and there has been a case or

two which calls for criticism. To regard a visit to the polar regions as part of a scientific training is well enough, but to take it as the whole training is far from well. There have been instances of young men who, with the sketchiest of training at home, have carried out their investigations in strange places and thereby acquired an authority in their science which is far from sound. This is not confined to the polar regions of course, and in the long run does not necessarily lower the prestige of science. It is not, in our opinion, so vital a criticism as the corollary to it, namely, that a very large proportion of the work done in the field is never published, and much of the collecting is lost to all but a small circle.

The blame for this must be shared between the authorities who lend their support to the expedition, the men themselves, and the scientific public. It is still somewhat unusual to find a leader looking beyond the end of his expedition and considering means of publishing his results. There have been some notable exceptions, and one may be permitted to single out some of the expeditions organized by the Oxford University Exploration Club, which have, by hook or by crook, published fairly full accounts of their work in the proceedings of learned societies. At the same time, some of the less-known expeditions with equally valuable work have been unable to get their work published, from lack of money or influence.

There is, in fact, a very strong case here for a General Publication Fund, the officers or trustees of which would receive applications for aid in publication. Much of the work is best placed in the journals of societies, but some is not quite suitable. The workers themselves should in any event see that their notes, if not published, are preserved in an appropriate place, such as a learned society or the Scott Polar Research Instituté.

There is yet another criticism which has appeared in print and should be met. It has been asserted that the parties do not go far enough afield, being limited practically to the longitudes from West Greenland to Spitzbergen. It should be realized that there is not a single part of the Arctic except Arctic Canada which is under the jurisdiction of the British. It is therefore only with the permission of Denmark, Norway and Iceland that these parts have been visited. Those countries have been very generous indeed in the past with permission, and the case for any reluctance they have shown has never been fairly stated on their behalf. They,

in common with Canada, have never really objected to properly authorized expeditions with a good and definite purpose. Nevertheless, since they must share some of the responsibility for the safety of the party as well as for the character of the work done, they do insist on support and authorization from responsible bodies. It is to be feared that there have been cases where a body has supported an individual or an expedition without sufficiently careful inquiry into antecedents and suitability for the work.

To sum up, it will have been evident that the post-War spate of polar exploration has been spontaneous and has all the merits and demerits of spontaneity. There is reason for a measure of control in so far as thorough inquiry into

prospective expeditions goes, but over-control is likely to dry up the enthusiasm and the freedom of selection which has been such a marked feature of the work.

The authorities who support expeditions are to be congratulated on the results so far; but it is to be hoped they will realize the necessity for a helping as well as a guiding hand in the matter of putting the results gained to the best use. Last and by no means least, our admiration is due to the comparatively small band of leaders of these expeditions who have triumphed over a myriad difficulties even before reaching their goal, and who, when there, have in nearly every case set an example to their men of enthusiasm, hard work and cheerfulness.

Protection against Air Raids

Civil Defence :

a Practical Manual presenting with Working Drawings the Methods required for Adequate Protection against Aerial Attack. By Capt. C. W. Glover. Pp. xx+308. (London: Chapman and Hall, Ltd., 1938.) 15s. net.

THE title of Captain Glover's book is somewhat misleading. He has written a manual containing many useful tables, facts, diagrams and illustrations which deal almost entirely with the protection of human beings, and to some extent of animals, against air attack. Civil defence, however, embraces many other urgent problems. The protection of men and women, especially those whose work enables the nation to resist an enemy, is an essential part of civil defence. But the supply of food and the maintenance of transport for its distribution; provision of electricity for essential works; continued output of aircraft; armament and other factories of national importance; the storage and import of oil; and safety and repair of the utility services; all are as much a part of civil defence as the protection of human life. Within this limited aspect, however, Captain Glover deals with many problems; and although the general reader may perhaps be put off by the jazz paper cover, which depicts a nightmare of steel cupolas, underground tube shelters, gas-proof doors and batteries of air filters, the bolder A.R.P. instructors, engineers and workers will find much that will be of use to them in the book.

After a chapter on the probable forms of attack, which includes an interesting statistical summary

of the raids made on London in 1915-18, and a description of the various types of bombs and their effect, Captain Glover goes fully into the question of gas. Some 300,000 substances were investigated during the Great War of 1914-18, and of the dozen or so that were adopted as being of practical use, about six were notably successful. Of these, the vesicants, such as mustard gas, caused the greatest casualties per ton used. On an average, it took 500 lb. of H.E. or 60 lb. of mustard to disable one man, but the ratio of deaths to total casualties was twelve times less for gas than for non-gas cases. He therefore deduces that gas warfare is both effective and humane, and must be expected to play an important part in future wars. Details of gas-proof rooms, filter appliances, gas masks, emergency lighting and the cost of the gas and fire-fighting appliances sold by a variety of firms are given.

The second half of the book deals with buildings, trenches and shelters. Of buildings, those which are multi-story, steel-framed or of reinforced concrete are considered the most suitable both for resistance and for containing shelter accommodation. Provided the walls are splinter-proof, that is, 12 inches of ferro-concrete or 14 inches of brick, the ground floor in buildings without basements is recommended as the best level for a shelter, and the stair well gives the greatest protection. But the floor above the shelter must, as in basements, be capable of holding up the debris that may fall on it. The author favours the Swiss standard of strength required for these shelter roofs, which is considerably in excess of

that suggested by the British and German regulations. He also adds the concentrated load of 15-20 tons on a circle of 10 inches in diameter. This would only appear applicable in the case of factories and other premises where heavy machinery or fittings may fall from the upper floors.

Two types of lay-out for trenches are given; of these, the zig-zag has been found in Spain to provide greater safety than the crenellated type when considering the radius of damage from a direct hit. In various plates, such as Figs. 70 and 61, the provision of a burster layer, or thick concrete casing which is not bomb-proof, is apt to create a false impression of security. It is a sound principle, where bomb-proof protection against a direct hit cannot be provided, to keep the shelter roof as light as will hold up the splinters and debris that will fall upon it. With trenches in the open, about 18 inches of earth is sufficient. The more there is, the more difficult it is to dig people out in the event of a collapse.

On the subject of dispersal, Captain Glover gives an interesting table which shows that a number of small splinter-proof shelters gives a better chance of safety than a smaller number of larger ones. Prof. J. B. S. Haldane, on the other hand, basing his opinion on statistics and the

theory of probability, considers this a fallacy; and in his recent book, "A.R.P.", states that dispersal within a dangerous area does not reduce the probable number of casualties. Mathematically, Prof. Haldane is probably right. But from a psychological point of view, casualties over a large area are less disheartening than very heavy losses in one spot, and from a practical point of view, small dispersed shelters are easier to find or construct than larger ones. In practice, a battalion commander who kept his battalion in mass under long-range bombardment would not remain in command long. Generally speaking, in factories and public shelters, not more than fifty people should be accommodated in one place; where trenches are made, separate ones for each fifty are probably better than a connected system.

Chapter xi gives the responsibilities of the layman and recommendations for the protection of animals. These will be of use to townsmen, but farmers would probably have apoplexy at the suggestion that their farm roads should be concreted to facilitate decontamination and that their pigsties be made gas-proof. The book ends with the Home Office organization of A.R.P., details of various poison gases, a bibliography, and a useful index.

E. H. K.

Teaching Methods

(1) Interpretation in Teaching

By Dr. I. A. Richards. Pp. xxii + 420. (London: Kegan Paul and Co., Ltd., 1938.) 18s. net.

(2) Creative Teaching: Industrial Arts and Vocational Education

By Dr. F. Theodore Struck. Pp. xxv + 623. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1938.) 17s. 6d. net.

THE problem with which Dr. Richards deals is one that receives attention in the recent Spens report on secondary schools. The pedantry and formalism of the traditional teaching of grammar and of rhetoric (and to some extent of logic) have done much to kill these subjects as elements in the general curriculum and thus to create a gap which urgently needs filling. Whether or not the exercises of parsing and analysing sentences should be carried out in schools, it is clearly necessary that the art of comprehending and discussing meanings should be acquired in the course of education.

This book has the originality and liveliness which is characteristic of all Dr. Richards's work. He

has set problems in comprehension and expression to members of adult classes and discusses the results. From these he draws conclusions as to the nature of the difficulties to be met with in acquiring these arts and the ways of overcoming them.

The book itself is an object lesson in a living method of teaching grammar, rhetoric and logic. Probably most of its exercises are very much too difficult for any except the highest forms in schools; but the intelligent school teacher could easily devise his own exercises on the same principles, suitably graded for the mental ages of his pupils. Dr. Richards makes the interesting suggestion that a valuable exercise in comprehension may be provided by translation into Basic English. It is worth considering whether translation into Basic English might, at smaller cost in school time, provide the advantages to comprehension which have, in the past, been given by translation into Latin.

(2) Dr. Struck's book deals with vocational education. It is didactic, forceful and analytical. The author gives eight characteristics of the progressive teacher, nine objectives of the industrial arts,

eight means of up-grading vocational teachers, and so on.

There is much in this that may profitably stimulate self-criticism in other teachers than those of vocational schools. The book seems to be a summary of the writer's own educational

experience, and such a summary by an intelligent teacher is always of value. One wishes, however, that the author had written less of the general problems of teaching and treated rather more fully the special problems of vocational education.

R. H. THOULESS.

The Thermionic Valve: Principles and Practice

Moderne Mehrgitter-Elektronenröhren

Von Dr. M. J. O. Strutt. Band 1: Bau, Arbeitsweise, Eigenschaften. Pp. vii + 131. 12.60 gold marks. Band 2: Elektrophysikalische Grundlagen. Pp. v + 144. 13.50 gold marks. (Berlin: Julius Springer, 1937, 1938.)

THE thermionic valve is the classical example—it is even a heavily overworked example—of the everyday implement which sprang directly from the most academic physics. Its development from the useful diode to the revolutionary triode may not have been a calculated development. But the succeeding stages of advance have been guided by the ingenious and meticulous application, clearly reasoned and quantitatively evaluated, of modern physical knowledge. Of the political consequences of these developments, this is not the place to speak. Of the direct economic consequences it is sufficient to quote Dr. Strutt's estimate that a hundred and fifty million multi-electrode receiving valves are in everyday use.

To the progress through tetrode and pentode to the modern octode many nations have contributed, and the relative scientific and technical material is scattered throughout many periodicals. The Philips Laboratories in Holland, with a distinguished record of fundamental research and of technical development, have played a very important part in progress, and the author of this work has made many and notable contributions.

It is, therefore, peculiarly appropriate that the enlightened policy of the Philips concern, and the enthusiasm of Dr. Strutt, should put at our disposal in these two volumes the first connected account of the construction, characteristics and mode of operation of multi-grid receiving tubes, and of the electrophysical principles on which they are designed, computed and operated. Since the reconciliation of research and teaching has never yet been satisfactorily achieved, it would be ungracious to complain that the exposition shows signs of haste, that the arrangement of the material

might have been made more logical and convenient, and that the index in particular is ludicrously inadequate and ill-proportioned. When a leader in investigation takes time to write down for us an outline of his principles and practice, he has a right to claim immunity from criticism, alike of his haste to get back to his work and of his anxiety to tell us—however summarily in the later pages of the later volume—of the very interesting things that are in the foreground of his mind as he goes to press. The immunity should not be claimed by his proof-reader, who has done his work well but not perfectly, and a printers' error in the list of printers' errors strains tolerance. But these are small matters.

The first volume, on "Construction, Mode of Operation and Properties", treats these two latter subjects from the point of view of the static characteristics and tube data. In the second volume, on "Electrophysical Principles", the characteristics are derived from the constructional details by the application of the laws of electron-dynamics. This second volume has, as its second purpose, the tracing of the complicated motions of the electrons in multi-grid tubes, as revealed by calculation and measurement, and in particular by measurements in the short-wave region, which are shown to be of special value for the purpose.

Volume 1 is divided into three sections, dealing respectively with high-frequency amplifying tubes, mixing tubes ("The mode of operation of a mixing tube is always this, that the slope of its characteristic varies with the rhythm of the oscillator frequency") and tubes for low-frequency power amplification. The treatment is very generously illustrated by constructional and circuit diagrams, and above all by a wealth of characteristic curves and operational data. These are plotted with a greater variety of parameters, as abscissae and ordinates, than is usual, and the variety compels the close attention and stimulates the individual thought of the reader.

Volume 2 proceeds from the fundamental equations, with mechanical analogies, through

examination of the electron motions in diodes (without and with treatment of initial velocities, and under the condition of constant emission temperature at the cathode) in triodes and in the ideal tetrode. Static and dynamic tube capacities are discussed, and important and interesting sections are devoted to the characteristic tube admittances in the short-wave region and to dynamic measurements of the electron motions in hexodes, heptodes and octodes. The last few sections include brief examinations of transit-time effects, of the relatively new, rapidly widening and extremely promising field of secondary-emission tubes, of the vital question of fluctuation-noise and the construction of low-noise tubes, and of some important thermal problems in multi-grid receiving tubes. It is significant to observe that the utilization of secondary-emission phenomena has already made commercially available tubes of exceptionally high mutual conductance

(14 milliamperes per volt), and tubes of exceptionally low noise-level.

The work is made still more valuable by the use of practical units, by the prominence given to numerical evaluation throughout, and by the provision of a bibliography of approximately three hundred independent entries.

These volumes are indispensable to the circuit designer who wishes to make the best use of the lavish gifts showered on him by the valve-physicist. But it makes good reading for a much less specialized circle; to trace throughout the work the whole story of the octode, its growth from less complex multi-grid tubes, the interactions and secondary effects which must be considered in its design, is an exercise which will impress any physicist with the high quality of the scientific insight and diligence which are so generously and compactly built into the modern multi-grid receiving valve.

A Study of Drugs

A Text-Book of Pharmacognosy

By George Edward Trease. Third edition. Pp. x + 740. (London: Baillière, Tindall and Cox, 1938.) 21s.

IT is a far cry from the *materia medica* of the old days to the modern pharmacognosy. The change has come about largely as a result of the policy of the Pharmaceutical Society of Great Britain in setting this subject on a scientific basis and in demanding a high standard of attainment in it in its qualifying examinations.

The chief exponent of pharmacognosy in Great Britain for some time was the late Prof. H. G. Greenish, who developed the teaching of it at the Society's School of Pharmacy in Bloomsbury Square. He lived just long enough to revise his valued text-book of pharmacognosy in the light of the 1932 edition of the *British Pharmacopoeia*. Since his death, his successor, Mr. T. E. Wallis, has continued to enlarge the scope of pharmacognostical practice, especially in the field of quantitative micro-analysis. Simultaneously, developments have occurred in the schools of pharmacy in British and foreign universities and colleges.

Mr. Trease's book has largely replaced that of Greenish in the teaching institutions. It was first published in 1934 and has gone through two editions in four years. The present edition is fully

abreast of the recent advances in pharmacognosy, and much time and thought have been devoted to its production. The complete pharmacognosist is a man of many parts. His preliminary training in botany, zoology, chemistry and physics furnishes him with a foundation on which to build experience in the technique of microscopy, histology, morphology, taxonomy, descriptive botany, plant geography. He learns how drug-yielding plants are cultivated, how the drugs are collected, prepared, exported, stored, marketed. He must know something of their active principles and the chemical tests by which they are recognized, and he must be able to appraise quality, and detect sophistication or substitution, particularly in relation to powdered drugs.

The author has gone to great pains to secure accurate information, and has obtained the help of several collaborators who have special knowledge. He presents his subject-matter in an interesting and readable form, illustrating it where possible by numerous reproductions of photographs, drawings and diagrams. The text-book is of great practical as well as theoretical value. It is almost indispensable to students of pharmacognosy; but the older pharmacists as well as all botanists would do well to peruse it. The publishers also are to be congratulated on a carefully printed and faithfully illustrated volume.

W. O. HOWARTH.

The Culture of Cities

By Lewis Mumford. Pp. xii+586+32 plates. (London: Martin Secker and Warburg, Ltd., 1938.) 21s. net.

MR. MUMFORD is a disciple of Patrick Geddes. In "The Culture of Cities" he applies the principles of his master to the problems of the aggregations of man as city-dweller. He follows the growth of the city community as it has developed in the past, and then sketches the ideal in an essay of constructive reform.

The greater part of his book—that is the first four chapters, covering some three hundred pages—is devoted to the description of the four types into which he classifies cities as examples of communal association, and analyses the various characteristics of each type, tracing their consequences as forces moulding the life and character of the citizen. Of these types, the first is the medieval, which, as the author points out, was never far divorced from the countryside; the second is the city of court and parade, such as Paris under the ancient regime; thirdly comes 'Coketown', the product of the growth of industrialism and the assemblage of some of the most degrading conditions in which man can exist; and lastly 'Megalopolis', the contemporary city of banking and finance.

In this examination of cities of the past and present, Mr. Mumford not only shows himself to be a keen critic and acute analytical thinker, but also he gives evidence of a wide and profitable experience of many men and cities, which he brings to bear rationally on his conception of the ideal in form in relation to the needs of human development. What may perhaps be regarded as the pivotal principle of his conception is the necessity of communal control of the land—a principle to which we seem to be approximating, but with, some may think, fatal deliberation.

Wild Animals in Britain

By Frances Pitt. (British Nature Library.) Pp. viii+120+68 plates. (London: B. T. Bataford, Ltd., 1938.) 8s. 6d. net.

THIS addition to the "British Nature Library" is uniform in make-up with Seton Gordon's "Wild Birds of Britain" and Robert Gathorne-Hardy's "Wild Flowers in Britain", and it has attained the same standard of almost unique beauty of production and considerable usefulness.

But the team responsible for the book was almost bound to produce the gem that this is. It is now traditional that a Bataford book on any natural history topic is art and science combined to produce just the right thing. Most of the hundred photographs which adorn the text are by well-known Nature photographers, Millais's "Roe Deer" is reproduced as a frontispiece, and the coloured jacket is by John Nash, whose delightful colour lithographs and line drawings illuminate the companion volume "Wild Flowers in Britain".

The illustrations certainly form the perfect complement to the text of Miss Pitt, who needs no

introduction as a writer on natural history subjects. Scarcely a naturalist could have missed reading at least one of her many books, and hundreds of thousands of lay readers must have been charmed by her articles in various periodicals and newspapers. Here, as in all her works, Miss Pitt bases her descriptions chiefly on personal observation, thus making the text not only reliable but also intimate and charming. Anecdote and story mingle with text description in such a way as to give a scientific study which also stimulates friendly feeling towards the lower animals.

The book is deserving of the success which we feel sure lies ahead of it.

The Chemistry of Synthetic Surface Coatings

By Dr. Wm. Krumbhaar. Pp. 200. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1937.) 20s. net.

THE chemist is penetrating quite far into the paint industry, partly as the result of the introduction of synthetic materials, with the consequence that a good deal is known about such important subjects as the chemical reactions in the varnish kettle, driers, the surface chemistry of pigments and paints, and the physical chemistry of surface coating. These subjects form the headings of a practical little work by Dr. Krumbhaar, who is himself engaged in the industry in the United States, where the application of all sorts of new coating materials is very much encouraged. A pleasing feature of the book is a number of excellent descriptive photomicrographs.

The new knowledge has even reached the printing ink industry, where the traditional slow-drying linseed oil media are losing ground in favour of quicker drying vehicles based on synthetic resins: a useful chapter is allocated to these developments.

The book will be found both stimulating and informative.

The Children of Tane

Bird Life in New Zealand. By Mona Gordon. Pp. xii+250+8 plates. (London: J. M. Dent and Sons, Ltd.; Christchurch: Whitcombe and Tombs, Ltd., 1938.) 10s. 6d. net.

THIS book is written in a slightly romantic vein, making much play with Maori names; but it deals in an interesting manner with bird-life in New Zealand, particularly the forest avifauna and measures for its preservation. The clearance of woodlands has had a very serious effect on the native birds, and this has been aggravated by the introduction of alien species. Fortunately, several islands have been set aside as inviolable sanctuaries, although even on some of these great harm is being done to the vegetation by imported deer or goats.

Each sanctuary is described, with an account of its history and its present state. There are also chapters on such topics as the pollination of plants by birds, flightless birds, and migratory birds—under each of which heads New Zealand provides some remarkable examples.

Combination Tones in Sound and Light*

By Sir William Bragg, O.M., K.B.E., Pres.R.S.

WHEN two notes are sounded together, the listener may hear in addition other notes which are not overtones of either of the originals. They are combination tones, the frequencies of which are linear algebraic functions of the primaries. Let us denote the latter by m and n : a note of frequency $m - n$ is much more difficult to observe. There may be notes of other frequencies, $m + 2n$, $2m + n$. . . but these are weaker still. A full description of the effect is given by Jeans in "Science and Music", p. 287 *et seq.* It is possible to make experimental arrangements by which the existence of combination tones may be plainly demonstrated. Some of these arrangements are described in the present note.

The subject has had a curious history. Observation must be somewhat close and careful if combination tones are to be heard; this is no doubt the reason why no one described them before Sorge in 1745 and Tartini in 1754. Helmholtz was greatly interested in them and discussed them at length in his famous work on "Sensations of Tone". Koenig strongly opposed the theory which Helmholtz put forward in explanation. The point at issue was whether or no the extra tones were subjective or objective. Helmholtz claimed to have shown by experiment that they caused a response in tuned resonators; Koenig asserted that they had their origin only in the listener's ear. A number of other experimenters joined in the discussion. Lord Rayleigh, Waetzman, Edser and Rucker supported Helmholtz, while Preyer and Boesanquet sided with Koenig. Ellis, in the second edition of his translation of Helmholtz's book, devoted a long chapter to a reasoned comparison of the two theories.

In view of the vigour of the disputation it is strange to observe that, when certain conditions are satisfied, combination tones must have a real objective existence in the sense that resonators can be tuned to them. It is also true that, as Helmholtz pointed out, they can be generated within the ear, on account of the ear's peculiar structure. Certain preliminary conditions must be satisfied if the tones are to be objective, and it would seem that the long controversy was

maintained by failure to realize those conditions in all cases.

The discussion at last died away. It was not even referred to when fifty years later an exactly analogous problem was met with in wireless telephony and the discussion was repeated in full. The so-called side bands are combinations of the carrier wave and the audio wave, and in the sense already described, have just as real an existence. Still later, the phenomenon has been found again in the peculiar scattering of light known as the Raman effect.

The underlying principle is very simple. When vibrations of two different frequencies are imposed upon a medium as, for example, when two tuning forks are sounded, the chord consists only of the imposed frequencies and there are no combination tones in the air. But if during the production of sound the amplitude of one source depends at every instant upon the amplitude of the other, the combinational tones appear. In the first case the disturbance in the medium may be represented by

$$a \sin 2\pi mt + b \sin 2\pi nt.$$

In the second, there is sure to be a term of the form:

$$2c \sin 2\pi mt \times \sin 2\pi nt,$$

which is equal to

$$c \cos 2\pi (m-n)t - c \cos 2\pi (m+n)t,$$

and the combinational tones have an objective existence.

This conclusion is readily illustrated by experiment. In Fig. 1, A represents a coil seen edge-ways, through which either a steady current a , or an alternating current $a \sin 2\pi mt$ can be made to run. B is a smaller coil at right angles to A ; the centres of the two coils coincide. Through the second coil, either a steady current b or an alternating current $b \sin 2\pi nt$ may be made to run. The second coil can turn about a vertical axis which is perpendicular to the plane of the diagram. T is a cylindrical tube in which a slider s is mounted; the slider contains a piezo-electric microphone connected to a loud speaker. When B vibrates about its axis, which it must do if there are currents in the coils and one or both are alternating, the disk D flutters before the mouth of the tube. The tube, as a resonator, can be tuned by moving the slider.

* Friday evening discourse delivered at the Royal Institution on November 11.

In an actual experiment, the current of frequency $m = 250$ was taken from a high-frequency generator, that of frequency $n = 50$ was drawn from the lighting circuit. When the current in A was alternating and that in B was steady, the resonator responded to the 250 note. When the current in B was alternating, the response to the 250 note became much weaker but the resonator could be made to respond strongly to either 200 or 300. The torque on the B coil was proportional to

$$\sin 2\pi \cdot 250 \cdot t \times \sin 2\pi \cdot 50 \cdot t,$$

that is, to $\cos 2\pi \cdot 200 \cdot t - \cos 2\pi \cdot 300 \cdot t$.

The difference tone should be the stronger, other things being equal, because the equation of motion of the B coil may be written

$$K \cdot \ddot{\theta} = -c \left\{ \cos 2\pi(m-n)t - \cos 2\pi(m+n)t \right\},$$

where θ is the angular displacement and K is the moment of inertia of the coil and c is a constant; so that

$$K \cdot \theta = \frac{c}{4\pi^2} \left\{ \frac{\cos 2\pi(m-n)t}{(m-n)^2} - \frac{\cos 2\pi(m+n)t}{(m+n)^2} \right\}.$$

The movement of the disk at the mouth of the resonator can therefore be analysed into two harmonic terms, one of them having a frequency $m - n$ and an amplitude proportional to $1/(m-n)^2$, the other a frequency $m + n$ and an amplitude proportional to $1/(m+n)^2$. The response of the piezo-electric microphone, and the other electric and acoustic transformations of the energy which take place before the sound leaves the loud-speaker will alter the relative intensities of the two sounds, and will even introduce fresh combination tones; but the main effect is so pronounced that the verification of the theory is quite clear.

Fig. 1.

Fig. 2.

An effect depending on the multiplication of harmonic terms can also be shown in a second way (Fig. 2). The light which passes through a small square aperture in a screen is brought to a focus at a place marked A in the diagram. It is there partly intercepted by two tuning forks which are at right angles to one another. The beam of light is thereby restricted to a rectangle of which the sides may be denoted when the forks are vibrating by

$$a + b \sin 2\pi mt \text{ and } c + d \sin 2\pi nt.$$

The intensity of the light which passes on is therefore proportional to the product of these two expressions; and this product contains the term $bd \sin 2\pi mt \sin 2\pi nt$. The light falls on a photo-cell and produces an effect which is transformed into sound. The latter can be analysed by the piezo-electric resonator used in the first experiment. It is found to contain the frequencies m , n , $m - n$ and $m + n$.

If the two tuning forks are placed parallel to each other, the intensity of the transmitted light is proportional to $a + b + c \sin 2\pi mt + d \sin 2\pi nt$ and there are no combination tones due to the optical arrangement. There may be, however, faint combination tones due to the subsequent treatment of the energy in the detecting apparatus.

The way in which a detecting apparatus can generate accessory tones may be illustrated by the following example (Fig. 3). Suppose that a piezo-electric cell is inserted at the end of a short cylinder, and that a piston executes a harmonic motion, so that the volume of the air may be put equal to $v = v_0 + v' \sin 2\pi mt$. Then the pressure p , supposing the motion to be isothermal (though

Fig. 3.

it makes no difference to the general result if it be taken as adiabatic) is given by $pv = c$, a constant.

$$\begin{aligned}\text{Therefore, } p &= \frac{c}{v_0 + v' \sin 2\pi mt} \\ &= \frac{c}{v_0} \left(1 + \frac{v' \sin 2\pi mt}{v_0} \right)^{-1};\end{aligned}$$

and this when expanded shows overtones, although the piston itself moves in a simple harmonic motion.

Fig. 4.

If there are two pistons operating on the one chamber,

$$p = \frac{c}{v_0} \left\{ 1 + \frac{v' \sin 2\pi mt}{v_0} + \frac{v'' \sin 2\pi nt}{v_0} \right\}^{-1};$$

and this when expanded shows a system of combination tones.

The variations of pressure can be converted into a complex sound in which the tones appear.

When a tuning fork is held before the mouth of the resonating tube used in the first experiment, the octave overtone is readily found.

When two notes are sounded on a harmonium or organ, combination tones are generally heard, though some people find a difficulty, especially at first. The combination tones of a harmonium at the Royal Institution are greatly intensified when a microphone is placed on the case of the instrument and connected to a loud-speaker. The combination tones of harmonium and organ would seem to be due to modulation, as in the simple instance just given. The pistons of the model are in the actuality replaced by the to and fro surges of air from the sounding pipes or reeds. It seems that in the

instance just given the combination tones are of greater importance in the vibrations of the wood-work of the chest than in the air outside.

In the radio transmission of sound, modulation is a necessity. Sound waves can be converted directly into electrical oscillations of similar frequency, but it is practically impossible to put into such slow oscillations sufficient energy for effective transmission. Hence a carrier wave of high frequency is employed which is modulated by sound waves and carries to the receiving station the impressions which have been made upon it. The form of the modulated wave can be represented in the customary way by such a figure as the curve *D* in Fig. 4, which may be described—approximately only—as a disturbance having a periodicity equal to that of the carrier wave, and an amplitude which varies in accordance with the impressions made by sound at the transmitting end. Strictly speaking, the disturbance is the sum of a number of different waves. One of them has the frequency of the carrier wave, and is as a matter of fact useless. Others are combination tones, and these are the real carriers; and there are other derivatives present in relatively weak amount.

In Fig. 4, the harmonic curve *B* may be taken to represent the carrier wave, that is to say, the ether wave due to the oscillator of the transmitting station, and *C* the ether wave into which a harmonic sound is transmitted. The frequency of *B* is ten times that of *C*; in practice, the factor is very much larger. If the disturbances were merely added as represented by the curve *A*, the two would be quite independent in their effects at a receiving station: the wave *B* would be detected just as if there were no wave *C*, and would convey nothing. The wave *C* would be too faint for perception. But if by proper manipulation at the sending station a wave is produced which is the continuous product of *B* and *C*, as shown in the curve *D*, then the effect of *C* on *B* is detected at the receiving station, that is to say, the sound signal is received.

The curves *E* and *F* are harmonic curves of frequencies nine and eleven times that of *C*, being the difference and sum respectively of the frequencies of *B* and *C*; and *D* can also be obtained by adding *E* and *F* together. The receiving station can detect these two separately. They are combination tones. Technically they are known as 'side-bands'.

The Raman effect is based on the same principle.

The incident light of definite frequency excites a forced vibration of the same frequency upon the molecule which it meets. If the magnitude of the response to the impressed electric force depends upon some quantity in the molecule which is undergoing harmonic oscillations, as for example

some relative oscillation of the atoms in the molecule, modulation occurs. Lines representing combination tones are found on each side of the line representing the original frequency in the spectrum of the scattered light.

Some Scientific Researches in the Region of Mount Everest

By N. E. Odell

ANOTHER expedition to Mount Everest has returned, with the primary object still unattained. As in the case of the four previous main attempts (1921 and 1935 were reconnaissances), the weather conditions, associated last year particularly with a very early monsoon, must be held chiefly responsible for a further failure to reach the top of the world's highest summit. While understood to be essentially a mountaineering expedition, in the intervals of strenuously pursuing the main objective an effort was made by two members of last year's party to carry out a certain amount of scientific work. It is much to be regretted that such work, on the more recent expeditions to Everest, has been in no way encouraged, but rather discouraged, by those responsible both for their organization and their leadership.

During the 1938 expedition, I had the opportunity of continuing the geological work commenced during the Expedition of 1924, and furthered by L. R. Wager in 1933¹. A. M. Heron, of the Geological Survey of India, had on the first Expedition of 1921 mapped geologically the Tibetan area lying to the north of the Everest Massif², but the stratigraphy and structure of the main Himalayan chain hereabouts was left to his successors. In 1924, a detailed study of the crystalline complex of the main range in particular was commenced by me, and I published a provisional geological map of the district surrounding Everest itself³. This work was continued during last year's Expedition, and an extensive collection was made of the various petrological types representative of the metamorphic series of the district. It is a tragedy that on the return journey almost the entire collection was stolen from one of our camps by Tibetan natives, the theft being presumably in mistake for the cash-box! However, with material collected in 1924, as well as by Wager in 1933, a comprehensive study is now being made of this particular region, although there must necessarily be gaps caused by the above irreparable

loss. From the information available, it is hoped that it will soon be possible to give a fair, though incomplete, account of the stratigraphy and age, as well as the ruling structures, of this complicated and inaccessible portion of the Himalaya.

Briefly, the age of the Everest stratified series is not younger than Permo-Carboniferous, while the intrusive granitic rocks are probably Tertiary, and date from the movements of that age, both horizontal and vertical, which have given rise to such pronounced structures as the Everest Thrust Fault (discovered last year on the south side of Everest), and the great fault-scarps confronting Tibet in many places along the northern flank of the main chain. There is, however, much important work yet to be done on these problems.

As to glaciological observations upon the unusual glaciers of this greatly elevated yet nearly tropical region, a start only has so far been made. Unlike the glaciers of the temperate zone, those of the Everest region appear to be frozen throughout their mass, a physical condition which places them in the category of 'high polar' glaciers (Ahlmann). This condition would seem to give rise to a greater brittleness and a tendency, as in the polar regions, for the glaciers to move more by fracture and shear than by what approximates to viscous flow. Not more than rough measures of the speed of these glaciers have as yet been made. Another point of interest is that the steeply inclined solar rays and intense insolation, together with a high rate of evaporation consequent upon the great altitude, give rise to remarkable and unusual wastage effects on the surface of these glaciers, of which the giant ice-pinnacles, and other *penitente* forms are examples. These same factors, coupled with the condition of the ice, have given rise to the very peculiar 'troughs', veritable ice-valleys, that are such a remarkable feature of the glaciers of the northern side of the Himalaya.

The present glaciers appear to be in a state of stagnancy, or possibly extremely slow retreat. That they once extended much farther down their

valleys is clear from the evidence of moraine-shelves along the Rongbuk valley and elsewhere. These consist of four lateral moraines, or discontinuous portions of them, one above the other, occurring at heights of from 400 ft. to 800 ft. above the valley-floor. Whether these glaciers, during the maximum Pleistocene glacierization of the region, debouched far out towards the Tibetan plains is not, from the available evidence, at present certain.

As to the study of the widespread post-glacial gravels along the southern border of the plains, and the extensive valley-terracing in the drainage-basin of the Arun River, an immense field lies open for further research. Wager⁴ has discussed the evidence of warped terraces and its possible significance in the tectonic history of the region; and it was a matter for the greatest regret that I was prevented last year from continuing the work upon this very important problem. In the valley of the Chiblung Chu and elsewhere, however, data were collected which suggest that much of the terracing in those areas may have been due to climatic rejuvenation, consequent upon Pleistocene conditions, rather than to tectonic.

Apart from the usual temperature and other meteorological observations, particular attention was paid in 1938 to determinations of relative humidity with an Assmann psychrometer, kindly lent by the Meteorological Office. In the light of the findings of G. Seligman that under Alpine conditions 85 per cent relative humidity constitutes a critical point at which wind-slab avalanches may take place, an attempt was made to test the theory under high Himalayan conditions, and especially on the slopes of the North Col. Under the difficult conditions of last year, however, no satisfactory conclusion was reached. Moreover, it had been hoped to bring into use a special high-speed anemometer and so obtain for the first time quantitative values of the wind velocity across the face of Everest. But the exceptionally early arrival of the monsoon, before we had actually reached the North Col, prevented this being done.

In spite of a good deal of preoccupation with illness on the Expedition, and apart from his being a member of the climbing party, Dr. Charles Warren was able in 1938 to collect further physiological data to amplify that obtained by his predecessors. This is now being examined, in particular samples of alveolar air, and the results will be published in due course. Specialists in this branch of science will be the first to admit that a vast amount of additional data is required before anything like a full understanding of many aspects of high-altitude physiology can be obtained.

The foregoing outline of researches attempted and accomplished, often under the greatest difficulties, should, it is hoped, be sufficient to indicate that much valuable work remains to be done by future Mount Everest expeditions. The only branch of scientific investigation that can be said in any way to have been completed is the topographical mapping, which was commenced by the Indian Survey detachment in 1921, continued in 1922 and 1924, and concluded locally in 1935 by photogrammetric methods. The field data obtained in 1935 have, however, yet to be worked up cartographically. That there is still an enormous field for scientific endeavour in this unique and little visited region must be realized when it is stated that geophysical and archaeological researches have so far never been attempted there. As far as geophysics is concerned, we are in complete ignorance as yet in regard to the state of gravity on the high plateau of Tibet. A very few determinations of the force of gravity would help us in understanding how that immense tract remains in such an elevated position without, apparently, the support inherent in folded mountain ranges themselves. A couple of trained observers for this particular purpose would be all that are necessary. Moreover, observations of terrestrial magnetism would be of great interest and value, and would amplify the important results of this kind recently obtained by Dr. Wienert of the (German) Schöfer Scientific Expedition, now working in the neighbouring territory of Sikkim and Tibet⁵, apart from those embodied in the extensive magnetic survey across Central Asia by W. Filchner during the last twelve years⁶.

As to archaeological research, along the route through southern Tibet one sees relics of many ruined mud-walled towns and villages, quite different in style of architecture from present buildings and dating back without doubt hundreds of years. Many of these structures suggest fortification, and there appears to be much in their character to recall the 'limes' (forts) of eastern Sinkiang, as described by Sir Aurel Stein. The study of these would clearly yield results of great ethnographical and historical value, and amplify the work of Sven Hedin north of the Tsangpo River.

In addition to the above studies, a large amount of important ecological and other work in natural history remains to be done. Indeed no real naturalist has accompanied the Everest expeditions since 1924.

The objection of native prejudice, that is in some quarters brought forward against scientific work on these expeditions, has often been unduly exaggerated, especially in regard to geology. For actually, at various places in Tibet, both lay and ecclesiastical members of the community have

sometimes offered fossils and other odd rock specimens for sale to members of the expeditions. With due tact and care it is quite easy in the pursuit of one's investigations to avoid offending the more unenlightened elements of a people who still largely live in an atmosphere of the Middle Ages, and who have cogently declared that Western

civilization can do nothing for them but promote unhappiness.

Obituary Notices

Prof. E. B. Wilson, For.Mem.R.S.

BY the death on March 3 of Prof. E. B. Wilson, the United States has lost her foremost zoologist. During his long tenure of the professorship in Columbia University he made some outstanding discoveries in his science. He studied the growth and structure of the so-called 'trochophore' larva which is specially characteristic of the annelid worms. It is also found in the Mollusca, a group widely divergent in structure from the worms. Further, it occurs in the Polynoa Entoprocta and Phoronidea, and in a modified form it is seen in the Nemertinea. There can be no doubt that it represents in modified form the common ancestor from which all these groups diverged. If we put them all together, we see that in this way the origin of a large proportion of the Invertebrata is accounted for.

Prof. Wilson introduced the conception of 'cell-lineage' into embryology. By this is meant the study of the growth of a particular cell in the cleaving egg until it gives rise to an organ in the fully developed trochophore. He recognized two types of cell lineage which he termed respectively "determinate" and "indeterminate" cell-lineage. In the former type, which is characteristic of the trochophore group, each particular cell of the egg gives rise to a particular organ. The latter type is characteristic of the Coelenterata and Echinodermata. In this type up to a certain stage in the cleavage the cells are equipotential, that is, each of them can give rise to the whole organism.

In his later years, Prof. Wilson took up the study of the growth of the nucleus, because this is the sole carrier of heredity. This is proved by the case of the mammalian spermatozoon, which consists merely of a nucleus but which transmits all the characters of the father to the young organism. Prof. Wilson had as his colleague in Columbia University Prof. T. H. Morgan, whose famous theory of the chromosomes swept over America like a whirlwind. This theory was based on studies of the fruit-fly, *Drosophila*, and professors of "drosophily" have actually been appointed in some American universities. Wilson accepted with some reservations his friend's chromosome theory; but he was more conservative than Morgan, and refused to associate special characters with particular bits of chromosome. In 1913, Wilson received the honour of an invitation to deliver the

Croonian Lecture to the Royal Society, and he chose chromosomes as his subject.

Wilson's influence on the course of the study of embryology was very great. A large band of young workers in both the United States and Europe continued and extended his studies in cell-lineage. My own acquaintance with Wilson extended over a considerable number of years. I first met him in Naples in 1892 when we were fellow students in the Zoological Station. Afterwards, I met him in the United States when we were both members of the American Society of Zoologists and I was professor at McGill University in Montreal, a few miles from the American border. His ill-health and subsequent death were due to a tragic accident which befell him when he was conducting a body of students, men and women, on a cruise up the Pacific coast of Canada. On the return journey the boat struck a rock and foundered. Some of the students were drowned and others, including Wilson, had to spend hours in the icy water before being rescued. From this exposure, Wilson contracted rheumatism, which crippled him during the remainder of his life and ultimately led to his death. It is too sad to think of the additional work which he might have done had this accident not occurred.

E. W. MACBRIDE.

Prof. A. P. Coleman, F.R.S.

THE death of Prof. A. P. Coleman, emeritus professor of geology in the University of Toronto, will be regretted by all geologists, for he was one of the few remaining representatives of that school of teachers who had received their early training at a time when geology was still a self-contained study and had not differentiated into the varieties of interest that now divide us.

Born at Lachute, Quebec, and educated at Victoria University, Coburg, Canada, Coleman proceeded, as did many Canadians at that time, to Germany, where he obtained the Ph.D. degree of Breslau. On his return to Canada he was made professor of geology and natural history at his old University in 1888, and remained there until 1890 when he was appointed to the University of Toronto. His ability was early recognized both in England and in North America as is shown by, among other distinctions, his election to

the Royal Society, the award of the Murchison Medal of the Geological Society of London and the Penrose Medal of the Geological Society of America.

Like all of his generation, Coleman's geological interest was wide, and we have from his pen papers dealing with such contrasted subjects as ore deposits and paleontology, pre-Cambrian stratigraphy and Pleistocene geology. Wide as was the scope of his work, however, it is probable that he will be remembered most for two outstanding studies, the geology of the great nickel ore-field of Sudbury, Ontario, and the evidence and history of past ice ages. The mapping of the Sudbury district involved much more than a study of the ores themselves, for it necessitated the unravelling of the geological history of a most complicated series of pre-Cambrian strata which in its turn had far-reaching effects on the interpretation of the structure of the "Canadian Shield" as a whole. Notwithstanding the great amount of work that has been done in this area by the geologists of the Dominion Geological Survey, the Ontario Department of Mines and the International Nickel Co., there has been substantially no change made in the rock groups that Coleman differentiated in his map and report of 1913.

In assessing the merit of this study one has also to remember the conditions under which it was executed. When Coleman entered the field it was still the typical wilderness of northern Canada, without roads of any kind and, in much of the area, without even trails. Owing to the somewhat unusual topography also, canoeing did not provide that ready means of access which is common in Ontario and Quebec, so that Coleman had to carry his survey through mostly on foot. Notwithstanding these difficulties his map has survived the exacting demands made on it by mining engineer and prospector, and the only change of any moment has been the recognition of faulting in the south-western corner. Some more significant alterations have been made, however, in his interpretation of the origin of the ores themselves, and there are few geologists now working in the district who would accept his theory of the formation of the sulphides by liquation from the adjacent norite either through the action of gravity or by some form of filter-pressing.

In his other important study, that of the past ice ages, Coleman was the first to present conclusive evidence of the glacial origin of the Cobalt conglomerate and to show its similarities with Pleistocene glaciation. He was convinced that the tillite could be traced as a definite horizon throughout the Huronian rocks of Ontario, but some doubt has been cast on this thesis by Collins's identification of the Ramsay Lake conglomerate as an ancient regolith.

No reference to Coleman's work would be complete without a mention of his love for travel and exploration. He made a point of seeing for himself the most significant features of world geology and to this end travelled much in Europe, Africa, India, Australia and North and South America. It is this immediate familiarity with the field observations that is reflected in his most interesting book on "Ice Ages, Recent and Ancient" published in 1926, and one can well

guess that it was from the same source that he derived that enthusiasm that made him so highly esteemed and successful a professor in Toronto. He also had the happy gift of portraying the scenes he had visited with water-colour sketches, one of special interest being probably the earliest picture we have of Mystery Mountain (Mt. Waddington) in the Coast Range of British Columbia. He did not restrict his painting to scenery alone but also applied it, in dramatic fashion, to the illustration of his theories of ore genesis.

T. C. FLEMISTER.

Dr. Louis Fabry

We regret to announce the death of Louis Fabry, the well-known French astronomer. He was born in 1862 and belonged to a family that has given eminent men of science to their country, one brother, Prof. Charles Fabry, being the renowned physicist; another brother, Prof. Eugene Fabry, is a mathematician of repute.

At the early age of sixteen years, Louis Fabry received the degree of *Bachelier ès sciences*, and after various other academic distinctions he was appointed to the Observatory of Paris in 1884 as a student astronomer. Two years later he went as assistant astronomer to the Observatory of Nice, and in 1890 he took up work at Marseilles Observatory, from which he retired fourteen years ago.

Fabry's interests in astronomy were very wide and he wrote on a diversity of astronomical matters. In 1893 he was awarded the degree of *Docteur ès sciences mathématiques* for his thesis presented before the Faculty of Sciences in Paris, in which he showed that the absence of strongly hyperbolic orbits among the comets proved that these bodies were members of the solar system. In 1899 he dealt with the influence of his theory of cometary orbits on the hypotheses of cosmogony, and showed that the attraction of the distant stars and the lack of homogeneity in the primitive nebula, although not very considerable, were, nevertheless, not without influence, and their simultaneous intervention was sufficient to explain both the rotation of the sun and also the direct motion of the planets. In addition, these factors were responsible for causing the comets to deviate from the line which would make them fall towards the centre of the nebula, that is, the sun, and so prevented them from possessing perihelion distances that would otherwise have been practically zero.

Fabry did much useful work on minor planets, in particular, in the compilation of tables for facilitating the computation of ephemerides. The improvement of orbits by means of four observations is a well-known method but it involves rather complicated algebraic calculations. Fabry partly overcame this difficulty by means of new differential formulae which introduced considerable simplifications in the solution of the problem. The method was later applied with great success by other computers. His tables on the perturbations of minor planets with small eccentricity and also small inclination proved very effective for the computation of the orbits and

ephemerides of these bodies. Amongst his other lines of research may be mentioned his work on refraction, his tables for the determination of the geographical visibility, measurement of altitudes by the barometer, studies in certain problems of seismology, and also his zenithal apparatus, described in the *Bulletin astronomique*, 12, 148, which was capable of making observations simultaneously of the zenith and stars in the vicinity. He was four times awarded prizes by the Paris Academy of Sciences. Astronomical science has lost one whose versatility contributed so much to its progress.

M. D.

Prof. N. V. Nasonov

PROF. NICOLAI VICTOROVICH NASSONOV, who has recently died in Leningrad, was the oldest member of the Russian (now U.S.S.R.) Academy of Sciences. He was born at Moscow on February 27, 1855, and in 1874 entered the University of Moscow where he studied under the well-known zoologist, Prof. A. P. Bogdanov, and on obtaining his degree was appointed an assistant and later a lecturer at the Zoological Museum of the University. In 1889, Nasonov joined the University of Warsaw and a year later was appointed to the chair of zoology. In 1909 the Academy of Sciences elected him to membership and he was called to the post of the director of the Academy's Zoological Museum at St. Petersburg. A strenuous period of reorganising the Museum occupied his time until 1921, when he became director of the Special Zoological Laboratory of the Academy which had been founded by the famous A. O. Kovalevsky. By 1925 this Laboratory, which at first occupied three rooms and had a staff of three men of science, had developed into a large Laboratory of Experimental Zoology and Animal Morphology. It was only in 1935, when eighty years of age, that N. V. Nasonov was persuaded by his medical advisers to retire from active administrative work, but even then he continued researches on regeneration until his death.

The published works of N. V. Nasonov are more than a hundred and seventy in number and deal with a variety of subjects. His earlier morphological work was mainly done on insects and other Arthropoda (ants, Strepsiptera), but later he produced excellent papers on sponges (Clonidae), on the development of the ostrich, on the anatomy and systematics of Turbellaria, a monograph of the wild sheep of the Old World, to mention but some of the problems investigated by him with painstaking accuracy and discussed with a broad evolutionary outlook. During the latest period of his work at the Zoological Laboratory, N. V. Nasonov concentrated his attention on regeneration problems, and published a series of outstanding contributions dealing with physiological factors of regeneration, with the morphogenetic function of cartilage, etc.

N. V. Nasonov was well known beyond the borders of his own country, since at various times he visited and worked at the biological stations at Trieste, Marseilles, in the museums in London (1913) and Berlin, and carried out expeditions to Egypt, Sinai and Japan.

N. V. Nasonov's death means the loss of one of the oldest generation of Russian men of science who in the second half of the last century laid the foundation for the development of biological sciences in that country, and whose work served to create for Russian biology an honoured place in the front rank of world science.

B. P. UVAROV.

Prof. H. A. Cummins, C.M.G.

WE regret to announce the death of Prof. Henry Alfred Cummins, emeritus professor of botany in the University College, Cork. He was a member of a family prominent in Cork medical and university life. An elder brother was professor of medicine in the same College.

Cummins was born in 1864. Having taken the M.D. degree in the Royal (now National) University of Ireland, he joined the Royal Army Medical Corps, and was immediately plunged into a series of campaigns. He served in the Sikkim Expedition (1888), Ashanti (1895-96) and in the South African War (1899-1901), during which he was mentioned in dispatches. On the outbreak of the Great War he was recalled for service with the R.A.M.C., and was again mentioned in dispatches. During his military career, he cultivated a keen taste for botany, and managed to collect specimens wherever he might be, even going so far as to shoot epiphytes, otherwise inaccessible, from high forest trees.

In 1909, shortly after his retirement as Major, Cummins was appointed professor of botany in University College, Cork, a constituent college of the National University of Ireland. He held this position until 1931.

Cummins had a personality of considerable charm. He followed his original interests in spermatophytes with histology and cytology. Just before his retirement, he carried out experiments on the reclamation of estuarine shores near Cork by means of the rice grass, *Spartina Townsendii*. These appear to have been the first attempts at such reclamation in Ireland.

J. C. SPERRIN-JOHNSON.

WE regret to announce the following deaths:

Prof. F. J. Cheshire, O.B.E., formerly director of the Optical Engineering Department, Imperial College of Science, London, on March 24, aged seventy-eight years.

Prof. Vasili Y. Danilevsky, of Kharkov, known for his work in physiology and endocrinology, on February 25, aged eighty-seven years.

Mr. L. J. Newman, Government entomologist of Western Australia, on December 8, aged sixty years.

Baron Joji Sakurai, honorary professor of chemistry in the Imperial University of Tokyo, president of the Imperial Academy and the National Research Council of Japan, on January 28, aged eighty years.

Prof. John H. Schaffner, professor of botany in the Ohio State University, an authority on the taxonomy and phylogeny of the Ohio and Kansas flora, on January 27, aged fifty-five years.

News and Views

Social Relations of Science

FOR many years past, the columns of *NATURE* have borne witness to the growing importance of science in everyday life, and the corollary that men of science should interest themselves actively in the social implications of their discoveries has been frequently urged. That they are not indifferent to the movement was apparent from the discussion on the subject in *NATURE* of April 23, 1938, and from the decision, taken by the General Committee of the British Association at the Cambridge meeting last summer, to establish a Division for the Social and International Relations of Science. The circumstances of the formation of the Division are stated in *NATURE* of August 27, 1938, p. 380. It was very appropriate that the first chairman of the new Division should be Sir Richard Gregory, who was editor of *NATURE* when the subject was discussed in these columns, and it was equally appropriate that he should open the first public meeting of the Division, held in the University of Reading on March 28, when various aspects of the utilization and production of milk were described by half a dozen leading authorities. The highly controversial subject of pasteurization received a considerable amount of attention, and rightly so, for it is with such problems, involving scientific, economic and even political issues, that the Division may be expected to deal. Indeed, one of the prime reasons for the existence of the Division, namely, the need, in controversial issues, for propaganda based on scientific facts rather than personal points of view was well exemplified by this first meeting. It was announced that further meetings of the Division are being arranged to be held in London in May and in Manchester in June.

Henry Edward Armstrong Memorial Fund

It is proposed to establish a Trust Fund to the memory of the late Prof. Henry E. Armstrong. At the Finsbury Technical College, and later at the Central College, South Kensington, Armstrong and his co-workers, Ayrton and Perry, tried out and established the principles of technical education in Great Britain, and thus encouraged the foundation of polytechnics and technical colleges throughout the realm. Friends, old colleagues and past students have decided to establish a Trust Fund to perpetuate the memory of his dynamic personality. The aim, financially, is a modest one, so that all, including those who met him in other walks of life, may feel that they are contributing an integral part to the memorial whatever the dimensions of their individual contribution. The hope is for a memorial fund totalling about £3,000. This will provide a guarantee fund to give, as it accumulates, sufficient to ensure the publication (or to give substantial financial assistance in the publication or preparation) of any original works, within the ambit of Prof. Armstrong's recognized interests,

that would not otherwise see the light of day. It will also be within the terms of the Trust to arrange for suitable public lectures by the authors of the works. An additional detail of the plan is that the publication itself will carry as frontispiece a portrait of Prof. Armstrong, a biographical note and a reference to the foundation and objects of the Trust. Furthermore, the fund will provide for a memorial plaque, or bust, for the City and Guilds College, South Kensington, and perhaps replicas elsewhere. The administration of the fund, it is proposed, shall be undertaken by six persons, one each from the Council of the Royal Institution of Great Britain; the Royal Society; the City and Guilds of London's Institute; the Royal Society of Arts: one additional member whom the above representatives may appoint and the author of the most recent work published under the Trust. Subscriptions should be sent to the Hon. Treasurer, Sir Alfred Chatterton, The Coppice, Beckenham, Kent.

The Gatty Marine Laboratory, St. Andrews

MARINE biologists will be pleased to learn that preparations are being made to reopen the Gatty Marine Laboratory at St. Andrews, and that it is hoped to have it in full working order when the British Association meets at Dundee this year. The laboratory, which has been closed for some twenty years, was built in 1896 and presented to the University by Dr. C. H. Gatty. It replaced the wooden building (previously a fever hospital) on an adjacent site where the late Prof. W. C. McIntosh established in 1884 the first permanent marine laboratory in Great Britain. St. Andrews has been a classic ground for the marine naturalist ever since the time of Edward Forbes, nearly a century ago. It is true that with the decay of the local fishing industry and the increasing pollution of the inshore waters due to the growth of the city the facilities for collecting are not so good as they used to be; but the interest of the locality is by no means exhausted. It is to be hoped that Sir D'Arcy Thompson and Prof. R. J. D. Graham will be adequately supported in their efforts to make St. Andrews once again a centre of teaching and research in all that concerns the life of the sea.

Economic Aspects of Defence

A PAMPHLET, "Economic Aspects of Defence", by Mr. Harold Macmillan, M.P., directs attention to the economic factors which are involved in our present rearmament programme and to the futility of rearmament unless it is accompanied by an adequate foreign policy (London: Macmillan and Co., Ltd., 1939. 1s. net). In this respect, he is highly critical of the Government policy urging that as a result Britain has been growing weaker instead of stronger during the period of rearmament, and he urges that the first

step in the building up of our defence policy should be to recreate as quickly as possible the alliance of peace-loving powers in the League of Nations. He also urges the importance in rearmament of simultaneous attention to the problem of unemployment. By a full utilization of the labour-power of those now unemployed and by the elimination of waste due to competitive redundancy in production and distribution, we could increase our production of armaments and of consumers' goods as well. The available labour power and capital resources of the nation should be distributed according to a plan of increased national productivity. Defence preparations, he insists, involve consideration of overseas trade and our general economic relations with other countries; the productive efficiency of our economic system as a whole; the accumulation of supplies of storable foodstuffs and raw material and technical questions regarding the kind of war material to be produced, the location of the necessary factories and the organization of reserve productive capacity.

MR. MACMILLAN urges the creation of a single authoritative foreign trade organization which, under the general direction of the Overseas Trade Department, would bring together and combine the activities of the Import Duties Advisory Committee, the experts in charge of the Exchange Equalisation Fund's operations, representatives of finance to advise on foreign lending, and representatives of the exporters' selling organizations and of the importers' buying organizations. He reiterates the plea for a National Economic Council and urges an Industrial Reorganisation (Enabling) Act to afford industry the opportunity of putting its own house in order and achieving the necessary output, and discusses in some detail an attack on the unemployment problem. A Ministry of Supply is regarded as essential, and Mr. Macmillan stresses the compatibility of his proposals with the promotion of social and individual freedom. In his final chapter on nationalism or internationalism, he argues that a policy of static resistance is not enough. If a correct foreign policy sustained by adequate economic and military strength is the first task, this must be followed by the creation of the national foreign trade organization supported by a powerful internal economic organization conducted on rational lines for the full utilization of our capital and labour resources. These measures would enable us to evolve a method of economic collaboration which would eliminate the causes of war.

Social and Political Implications of Science

CONTINUOUS survey and co-ordination of teaching and research work of the University in the natural and social sciences in terms of its relation to the political and social problems of the day—such was the task undertaken in 1933 by a group of faculty members of the University of Wisconsin. They established an organization known as the "Science Inquiry" which has had the effect of concentrating the attention of much of the University staff on scientific problems facing the State and the nation.

A guiding principle has been that attacks upon such problems should be comprehensive rather than departmental so that instead of fragmentary findings "there may emerge at least the beginnings of integrated programmes with improved perspective and balance and with the application of these problems to State needs kept to the front". Among its publications are bulletins on the regional approach to conservation of natural resources, on transportation, and on the fight against crime; also (in preparation) international relations, public utility and power regulations, technological unemployment, communications, and consumption from the points of view of the producer and consumer. It is claimed on behalf of "Science Inquiry" that it has "evolved a group consciousness on the part of the faculty of common human problems which already is having a notable influence on the direction and emphasis of individual activities in teaching as well as research at the University".

U.S. National Youth Administration

A REPORT prepared for the Advisory Committee on Education of the United States by P. O. Johnson and O. L. Harvey on the National Youth Administration describes the organization and programme of the work of the Administration with a brief evaluation of some of its achievements. The National Youth Administration was set up as an agency within the Works Progress Administration in June 1935 and is thus primarily a relief agency, operating with funds earmarked for the general appropriation by Congress for emergency relief. Its two chief programmes are student aid and work projects, and its detailed operation in the several States varies according to local needs and problems. The number of young persons between 16 and 24 years of age receiving aid on the major programmes rose from about 470,000 a month in the first six months of 1936 to 580,000 a month in the same period of 1937 but has since declined owing to the reduction in the total budget. The student aid programme provides for those youths who are otherwise financially unable to continue their schooling. The work projects programme provides work experience for those whose interest in further schooling is relatively weak but who require work experience as a qualification for admission to private employment and earning a living. The guidance and placement service gives vocational guidance and attempts to place unemployed youth in employment. The apprentice-training programme was only an incidental function of the National Youth Administration and has recently been transferred to the Department of Labour. The programme of educational camps for unemployed women proved expensive to maintain and has been terminated for this and other reasons. The experiments have directed attention to many inadequacies in the provision for vocational guidance and, apart from the prevention of demoralization or restoration of morale, the National Youth Administration has demonstrated the possibilities of concerted action in the solution of the problems of youth, and particularly the value of proper direction and wise planning.

Recent Developments in British Surveying Instruments

BRIGADIER M. N. MACLEOD delivered the Thomas Young Oration of the Physical Society on March 24, taking as his subject "Some Recent Developments in British Surveying Instruments". Referring to the aerial camera as a surveying instrument, he pointed out that all parts of the ground must be photographed from two separate points. Plotting is done by combining, stereoscopically or otherwise, two such pictures. Plotting from tilted photographs requires complicated apparatus. In the first plotting machines the air positions of the camera and the direction of its optical axis had to be determined by a "resection in space" from control points on each photograph. There are theoretical as well as practical objections, however, to such independent determinations. In 1926, Dr. Fourcade propounded the idea of first determining the *relative* positions of the air cameras without reference to ground points, and devised a stereo-goniometer for this purpose. This principle has been made the basis of a new British automatic plotting machine constructed for the War Office and about to be delivered to the Ordnance Survey. In the majority of automatic plotters, the photographic picture is reconstructed stereoscopically and the image of a mark in the stereoscope is superimposed optically on the view. The visual or 'floating' mark can be moved about by the plotting mechanism and can be made to coincide in depth as well as in alignment with any point in the view. The apparent movements of the mark are transmitted mechanically to a plotting pencil. In all automatic plotters, however, much time is taken in the preliminary adjustment for reconstructing the stereoscopic view and determining its scale and orientation. It is hoped that the new instrument will enable this preliminary setting to be done decidedly more quickly than is the case in any existing foreign model.

Prehistoric Fire-Dog

COLONEL J. C. WYNN FINECH, a governor of the National Museum of Wales, has lent to the Museum for purposes of exhibition for a period of two years the remarkable example of Celtic iron-work known as the Capel Garmon fire-dog, which was found at Carreg Caedog Farm, near Capel Garmon, in 1852 by a labourer when digging a drainage trench. It is described (*The Times*, March 16) as constructed of two vertical bars, bent over at the top to form a neck, on to which is fastened a crest and the schematized head of an ox. The bars stand on semi-circular arched feet, and are connected by a horizontal bar thickened towards the middle, presumably to support the weight of the logs. The uprights are ornamented on each side by a ribbon of iron, bent in semi-circular loops, and with spiral coils at the top and bottom. The ribbon between the loops is attached to the upright by heavy decorative rivets. Other finds of a generally similar character have been made in south-eastern England in tombs belonging to the Belgic culture of the Iron Age, to be dated *circa* 100 B.C.-A.D. 50, while others, again approximately of the same period, have been found on the Continent

in areas occupied by the Celts, who seem in this instance to have adapted an object of Mediterranean type to their own uses. It is pointed out that the Mediterranean influence may perhaps be seen in a very special fashion in the crest of the Capel Garmon fire-dog, which with its thin vertical strip pierced at intervals with circular holes and bearing a thick bar flattened and curled at its lower end, and in its row of knobs representing the plume socket, suggests a Greek helmet crest. None of the fire-dogs so far discovered is as elaborate as the Capel Garmon specimen, as they lack the crest, the loops on the uprights, and the rivet-heads. The discovery of pairs of fire-dogs together suggests, although it is not known with certainty, that two formed a set, one being placed on each side of the fire, which was laid in the centre of the house.

New Egyptian Royal Tomb at Tanis

FURTHER details of the Egyptian royal tomb recently discovered at Tanis in the Nile Delta (see *NATURE*, March 25, p. 512) suggest that the results of its examination may prove of even greater interest than was anticipated at first. Another chamber has now been discovered and opened. It also proved to be intact. It is thought that the explorers may be fortunate enough to find still other chambers which have not been plundered; while there is the even more stimulating possibility that this may be the first only of a whole series of royal burials belonging to the twenty-first and twenty-second dynasties. Again, the walls both of the chamber in which the royal sarcophagus has been found and of that since opened are covered with paintings and inscriptions, from which presumably many historical data will be recovered, such as were, strikingly, absent from the tomb of Tutankhamen. Among those in the chamber of the sarcophagus is the cartouche of King Psusennes, identified with the King Shishak, who plundered Jerusalem in the reign of Rehoboam in 930 B.C. Many finely sculptured jars, some with beautifully carved stoppers, much jewellery of gold and precious stones and a huge sculptured human foot have been found. Within the silver mummy case of King Shishak was an inner casing of gold and leather. The first pictures of the tomb, funerary chambers and finds to reach England appeared in *The Times* of March 27.

Archaeological Expeditions to the East

THE departure for the East of two archaeological expeditions is announced, one proceeding to Iran and Afghanistan, and the other to Aden. Of these the former, conducted by Mr. Arthur Upham Pope, an authority on Sassanian art and archaeology, is the first section of a new architectural survey expedition of the American Institute of Iranian Art and Archaeology, of which Mr. Pope was one of the founders and the principal promoter. The members of the expedition will be engaged in studies preparatory to a complete history of Iranian architecture, a much-needed undertaking which, when complete, will contribute materially to the advancement of Iranian

cultural and historical studies. On the second expedition, Mr. L. P. Kirwan, a well-known archaeologist, will visit the Aden Protectorate for the purpose of inspecting and examining a number of archaeological sites between Aden and Lahej. He will visit Amadiya on the Andhali Plateau, which will be surveyed, and the ruins of Qohlan in Wadi Beihan. Mr. Kirwan will also examine and report on the archaeological material in the Aden Museum, which is now in process of being reorganized.

Exhibition of Chinese Art

AN exhibition has been arranged in the North Court of the Victoria and Albert Museum, South Kensington, which illustrates comprehensively the whole range of Chinese art from the prehistoric period at about 3000 B.C. down to modern times. With the exception of a small series to be seen in the Department of Ceramics, this exhibition includes all the objects of Chinese art of all kinds now in the possession of the Museum. It includes the Museum's share of the Eumorfopoulos collection, which provides some of the most striking and widely known exhibits. The arrangement of the exhibition is chronological and cultural. Each exhibit is grouped with others, whatever their character or material, whether of jade, textile, painting or pottery, provided they belong to the same period and are of the same cultural origin. The first and earliest exhibit is a neolithic pot of about 3000 B.C. A special feature of the exhibition is the important collection of ritual bronzes, which has been provided with special case-labels incorporating small photographs, illustrating the main features of style. A collection of Buddhist sculpture of the fifth and sixth century A.D. is on loan from Baron von der Heydt. Especially noteworthy are two wooden sculptures, one a figure of Kuan Yin, Goddess of Mercy, dating from the twelfth century, and a statue of a seated man, belonging to the fifteenth century. The exhibition is to be permanently on view.

British Museum (Bloomsbury): Recent Acquisitions

ACCESSIONS to the collections of antiquities and ethnographical objects in the British Museum (Bloomsbury) of exceptional interest were reported at the meeting of the Trustees on March 11. Of these one is a remarkably fine example of the Irish twisted gold torque, which has been accepted on loan for temporary exhibition from the Duke of Westminster. It is made from a single bar of gold, 50 inches long and weighing 26 oz. It has been chiselled and beaten into four flanges and then twisted and bent into a circle. The ends are recurved to fit into one another to form a fastening. It is of a type characteristic of the Middle Bronze Age and dates from about 1200 B.C. It was found in 1816 at Bryn Sion Farm, Flintshire. Another accession to the Department of British Antiquities is a collection of fragments of pots of dark earthenware, freely ornamented towards the top with hatchings, pitting, and finger-nail marks, presented by Mr. J. P. T.

Burchell. They were excavated by him in the Ebbsfleet Valley, Kent, at a depth of 10 ft. in stratigraphical conditions, which make it certain that this pottery is older than the neolithic period as at present understood. It is possible that this may prove to be the oldest pottery as yet found in Britain. It would seem to be connected with mesolithic types found on the Continent, such as those from the Danish kitchen-middens. It differs from British 'Neolithic A', and may indeed prove to be a predecessor of 'Peterborough' ware. Another accession of considerable archaeological interest is a human face, almost circular in outline, carved on a piece of Bath stone found near Charterhouse-on-Mendip. It has almond-shaped eyes and a small round hole for a mouth. It dates from the period of Roman occupation; but is thought to represent a native barbaric tradition. Of the ethnographical accessions the most striking is a wooden totemic figure of an eagle made by the Siwash Indians of Vancouver Island. It stands about four feet high, with wings half-spread, and is painted in gaudy colours, and has a fierce human face painted on the breast.

British Museum (Natural History): Recent Acquisitions

THE Mineral Department of the British Museum (Natural History) has acquired through Mr. Arthur Russell a small collection of foreign minerals from the collection of Philip Rashleigh, F.R.S., of Menabilly, near Fowey, Cornwall (1729-1811). The main part of the Rashleigh Collection is in the Truro Museum. Mr. Arthur Champion has collected rocks from various localities on a remarkable motor journey he made in 1937 from Dakar to Nairobi. The collection includes specimens from French West Africa and the Belgian Congo as well as from Senegal, Gold Coast and Nigeria. A fine specimen of the mineral thortveitite has been received from Prof. T. Vogt of Trondhjem, Norway, and suitable specimens have been sent him in exchange.

Broadcasting in 1938.

THE report of the Governors of the British Broadcasting Corporation for the year ended December 31, 1938, as presented to His Majesty's Postmaster-General, has recently been published as a white paper (Cmd. 5951. London: H.M. Stationery Office. 6d. net). The scope of the report is indicated by the headings of the main sections into which it is divided, namely, programmes, public relations, engineering and administration. During the year under review, the Corporation suffered a loss by the resignations of its first director-general, Sir John Reith, and of the deputy director-general, Vice-Admiral Sir Charles Carpendale. Mr. F. W. Ogilvie was appointed to the first position, while Mr. O. G. Graves became the new deputy director-general. The staff of the B.B.C. is now more than four thousand, and these have provided to nearly nine million licensed listeners a home broadcasting service of some 79,500 hours in 1938, with the remarkably small breakdown time of 0.028 per cent. In addition, nearly 33,000 hours

of Empire programmes were provided, while the aggregate time of operation for the television sound and vision transmitters has increased from 1,619 hours in 1937 to 2,679 hours in 1938. Among the increased programme facilities provided during the past year were daily news services in Arabic for listeners in the Near and Middle East, and in Spanish and Portuguese for listeners in Latin-American countries. Towards the end of the year, also, daily news services, intended primarily for European reception, were broadcast in French, German and Italian.

On the engineering side, a new medium wave transmitting station was opened at Aberdeen in September; and the construction of a new high-power transmitting station at Start Point in South Devon, and of a medium-power station at Clevedon, Somerset, is proceeding satisfactorily. The number of transmitters normally in use at the Daventry short-wave station has been increased from four to six, so that larger areas may be covered for longer periods. Further expansion is in hand at this station, including the provision of new transmitters and aerial systems. The scope of the television programmes has been considerably extended during 1938 by the provision of increased studio facilities at Alexandra Palace, by the purchase of a second mobile television unit for outside broadcasts, and by the establishment of improved relay link arrangements for such broadcasts. The report concludes with a statement of the financial position as at December 31, 1938.

Antarctic Whaling

THE *Polar Record* for January, a journal which has now widened its scope to include various articles in addition to news of polar expeditions, contains some details of the International Whaling Agreement of 1938. The measures agreed on in 1937 included a minimum size limit for various species, the restriction of the Antarctic whaling season from December 8 to March 7 and the prohibition of pelagic whaling in temperate and tropical waters. Last year the conference went further, though it was decided that restrictions on the numbers of whale catchers were impracticable at present. It was, however, agreed to prohibit the killing of humpback whales in waters south of lat. 40° S. for one year. This species is more vulnerable than blue and fin whales, and it is hoped thus to save the stock from exhaustion. It was also decided to prohibit all pelagic whaling for at least two years in the Pacific waters south of lat. 40° S. between long. 70° W. and 100° W. These waters so far have no pelagic or other whalers and so may well serve as a sanctuary for hunted species. In spite of these restrictions, it is admitted that the industry as a whole is probably taking an unduly large number of whales.

Australian Cancer Research

THE present position of organisations combating cancer in the Antipodes can be seen from the report of the ninth Australian Cancer Conference held in Sydney during April 5-8, 1938 (Canberra: Govern-

ment Printer, 1938). In many centres of the Commonwealth, new radiological plant has been installed and old apparatus improved, and attempts are being made to improve facilities for diagnosis in country districts. In an address given on the occasion of the Conference, Prof. E. C. Dodds pleaded for development of general research in basic sciences as being probably the best way of helping existing lines of cancer research. Dr. Robert Fowler discussed the research value of clinical records with particular reference to the 'follow-up' of cancer patients, and considered in some detail the indexing of cases. In a population of six and a half millions in Australia there were more than 7,500 deaths from cancer during 1936. A statistical examination of this cancer mortality was made by Dr. M. T. Holmes, who also summarized the results of treatment with radium at Australian centres over a nine-year period. Of 35,000 cases treated with radium, less than 10 per cent showed no improvement. Examination of data along similar lines should indicate how methods of treatment develop and how they compare with those of other countries.

The Dutch Physical and Medical Congress

THE twenty-seventh Dutch Physical and Medical Congress will be held at Nijmegen during April 11-13, 1939, under the presidency of Dr. G. Holst. General lectures will be given by Dr. G. Holst on "The Properties of Magnetic Materials" and by Prof. B. Brouwer on "The Significance of the Hydrodynamic Relations within the Skull Cavity and the Semicircular Canal for Neural Surgery" on April 11, and by Prof. L. S. Ornstein on "Physics and Biology" and by Prof. E. Gorter on "Very Thin Films" on April 12. The scientific work of the meeting will be dealt with in the four sections: Mathematical and Physical Sciences, Biological Sciences, Medical Sciences, Geological-Geographical Sciences, some seventy papers having been promised. A full programme of social functions, visits to factories, laboratories, hospitals and other places of interest has been arranged. Information can be obtained from the "Natuur en Geneeskundig Congresbureau", Bureau Vreemdelingenverkeer, Keizer Karelplein 9, Nijmegen, Holland.

Kathleen Schlesinger Research Fellowship

THE Medical Research Council invite applications for the Kathleen Schlesinger research fellowship which has been provided from a fund established by the late Mr. Eugen M. Schlesinger and Mrs. Schlesinger in memory of their daughter. It will be awarded to a suitably qualified person who will devote his or her whole time to "investigating the origin and nature of cysts of the brain whether arising from tumours or not or to such studies of other conditions of the central nervous system as the Council may from time to time permit". It will ordinarily be tenable at the National Hospital for Diseases of the Nervous System, Queen Square, London, and for a period of one year in the first instance. The stipend will be at the rate of £300 per

annum, with up to £50 per annum for research expenses. Further information can be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S.W.1.

Earthquakes in Japan and Greece

An earthquake, reported as the strongest for five years, shook several parts of the island of Kyushu at 12.22 p.m. local time on March 20 (3.22 G.M.T.). The shock was felt in Fukuoka but appears to have been strongest in Miyasaki where property and power lines were damaged and twenty people injured. The nearest active epicentre to this region appears to be $31^{\circ}8' \text{ N.}$, $131^{\circ}8' \text{ E.}$ where shocks occurred on 1929 5 m. 21 d., and 6 m. 11 d. There are three lines of weakness near the island of Kyushu according to Imamura: two pass through Nagasaki and run roughly east-north-east and south-south-east whilst the other is just off, and approximately parallel to, the south-east coast.

An earthquake shock of considerable intensity was felt on March 27 in Athens and other Greek towns though no great damage is reported. The epicentre of the shock was probably near Chalcis though very little information is at present available. It will be remembered that the centre of the disturbances on July 20, 1938, was near $38^{\circ}35' \text{ N.}$, $23^{\circ}8' \text{ E.}$, near Soala Oropos.

Royal Geographical Society: Awards

HIS MAJESTY THE KING has approved the award of the Royal Medals of the Royal Geographical Society as follows: The Founder's Medal to Mr. Arthur Mortimer Champion, for his surveys of the Turkana Province and the volcanoes south of Lake Rudolf; the Patron's Medal to Prof. Hans Ahlmann of Stockholm, for his exploration and glaciological studies in the Arctic. The Council has awarded the Murchison Grant to Mr. Robert Benthall, for his mapping and geological investigations in Ellesmere Land; the Back Grant to Lieut.-Commander R. E. D. Ryder, for his captaincy of the *Penola* and his marine surveys on the British Graham Land Expedition; the Cuthbert Peek Grant to Mr. W. Vaughan Lewis, for his physiographical studies in Great Britain and Iceland; the Gill Memorial to Mr. J. V. Harrison, for many years' exploration in Central and South America and Southern Iran.

Announcements

COLONEL J. A. MANFOLD has been appointed director of hygiene at the War Office in succession to Major-General H. H. A. Emerson, who will retire shortly.

THE Herbert Jackson Prize for 1938 of the L.M.S. Railway Co. has been awarded to Mr. J. N. Bradley, an assistant metallurgist in the Company's Research Laboratory at Derby, for his paper entitled "The Separation of Mixed Gunmetal and White Metal Borings". A Jackson Medal has also been awarded

to Mr. C. W. Newberry, research assistant in the engineering section of the same Laboratory, for a paper entitled "An Investigation into the Occurrence and Causes of Locomotive Tyre Failures". The Herbert Jackson Prize is awarded annually by the L.M.S. in memory of the late Sir Herbert Jackson (an original member of the L.M.S. Advisory Committee on Scientific Research), to a member of the Company's research staff for the best written account of an investigation carried out in the Companies' Laboratories during the year.

At the annual general meeting of the Ray Society held on March 23, the following officers were re-elected: *President*, Sir Sidney F. Harmer; *Treasurer*, Prof. F. E. Weiss; *Secretary*, Dr. W. T. Calman. Dr. John Ramsbottom was elected a vice-president, and Mr. E. R. Martin, Mr. D. M. Reid, and Col. R. B. Seymour Sewall were elected new members of Council. It was announced that a "Bibliography of the larvae of Decapod Crustacea" by Dr. R. Gurney, and the first of two volumes on "The Comity of Spiders" by Dr. W. S. Bristowe are in the press and will be published shortly. The first volume of a work on "British Water Beetles" by Prof. F. Balfour-Browne is nearly completed and will form the issue to subscribers for 1939.

THE University of Pavia has arranged a celebration in honour of the eighteenth-century physiologist, biologist and volcanologist, Spallanzani (1729-1799), which is to be held in Pavia on April 11-14. A monument to Spallanzani is to be unveiled and a programme of scientific addresses, mainly on modern genetical problems and the physiology of reproduction, is being prepared by delegates invited from various countries, including Prof. R. Ruggles Gates, Prof. F. A. E. Crew and Dr. C. F. Pantin from Great Britain. Meetings of the societies for experimental biology, botany, geology and veterinary medicine are also being held at the University, and on April 15 a visit will be paid to the Spallanzani Museum at Reggio Emilia.

IN 1937 the birth-rate in the U.S.S.R. was 18-19 per cent higher than in 1936 and the increase in population was a little more than 2 per cent. During the first ten months of 1938 there were 100,000 more marriages in the Soviet Union than in the corresponding period of 1937.

PROF. V. A. FOCK, of the University of Leningrad, writes that the transcription of his name in the article on the U.S.S.R. Academy of Sciences in *NATURE* of February 25, p. 343, namely, Fok, is incorrect and should be as here indicated.

ERRATUM. In the list of "Forthcoming Books of Science" in *NATURE* of March 11, p. 428, the volume by Prof. E. J. Conway to be published by Messrs. Crosby Lockwood and Son, Ltd., should be entitled "Microdiffusion Analysis and Volumetric Error".

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 564.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Activity of the Succinic Dehydrogenase

It has long been held that the succinic dehydrogenase requires no co-enzyme or intermediary hydrogen carrier to link its activity with that of the cytochrome system.

Ahlgren¹, however, working with a preparation made by extracting washed horse muscle with a solution of disodium hydrogen phosphate, found that with added succinic acid it induced an oxygen uptake which, though vigorous at first, rapidly fell to near zero. In the presence, however, of a *Kochsaff* from rabbit-muscle, the uptake was greater and much longer sustained, indicating that a thermostable factor may be necessary to complete the activity of the enzyme. He found, on the other hand, that the presence of the *Kochsaff* had no effect whatever on the rate at which the enzyme preparation reduced methylene blue.

Ahlgren's results have much interest but do not perhaps yield quite definite conclusions. The significance of the effect of muscle-*Kochsaff* as observed by him seems to be lessened by the experimental results we have to report.

We have ourselves obtained, from pigs' heart muscles and rabbits' skeletal muscles, preparations of the succinic enzyme which, in the presence of the substrate, actively reduce methylene blue anaerobically, but prove quite unable to induce any oxygen uptake, though in a system containing adequate concentrations of cytochrome c and its oxidase. In what follows, the method by which such preparations have been obtained will be briefly described, together with some details of their behaviour.

In an attempt to purify or concentrate the enzyme we have tried the solvent power of ethylene glycol, dodecyl sulphate, formamide, saponins and bile acids, and also glycerol and phenol. With the exception of bile salts, none of these was satisfactory. In our final procedure we have started with the muscle residue left after thorough extraction with sodium and lithium chlorides (Hopkins, Morgan and Mann)². This is first extracted with a solution of bile salts. In most experiments a commercial preparation of tauroglycocholate in 10 per cent solution was employed, but we have later used pure sodium deoxycholate (4 per cent) with advantage. The material insoluble in such solutions, being centrifuged off, the supernatant solution is clear, or shows at most a slight opalescence. It is cooled to 0° C., and mixed with an equal volume of ice-cold ethyl alcohol. The resulting precipitate is centrifuged off and washed with cold alcohol until free from bile salts. The alcohol precipitate is then extracted with 20 per cent urea solution. Finally, the urea is removed by dialysis and the precipitate, which rapidly separates, constitutes the preparation used in our experiments.

It is insoluble in water, and we have employed it in the form of a milky aqueous suspension.

It is easy to show that a factor not involved in the activation of the succinic acid hydrogen atoms, but essential for their transfer to the cytochrome system, is, at the stage of extraction with bile salts, dissociated from the enzyme and is itself not soluble in bile salt solutions. That the hydrogen activation is independent of such a factor is made sure by the consistently high activity of these solutions as displayed by the Thunberg technique, in spite of the fact, which separate experiments have shown, that bile salts somewhat inhibit (reversibly) the enzyme activity. The failure of hydrogen transference can be shown spectroscopically or manometrically. The chloride extracted muscle reduces cytochrome freely, but if to the bile solution (with substrate) oxidized cytochrome be added, there is no reduction at all, or, at most, a very slow and feeble one. It is easy to show that the cytochrome oxidase is present in these bile extracts.

Manometric results demonstrate unequivocally that, in a system containing succinates, cytochrome and its oxidase, the bile salt solution induces no oxygen uptake. This is equally true of our final preparation in spite of its high activity with the methylene blue technique.

The addition of methylene blue (1 mgm. in 3 c.c. of solution) to a system containing the purified product results in an oxygen uptake which, though relatively slow in the bile solution, is rapid in the final preparation. None of the known coenzymes can act as the missing carrier of hydrogen, nor can glutathione, vitamin B₁, adrenaline, ascorbic acid, nicotinic acid amide. With flavin-adenine dinucleotide a slight but probably not a significant uptake of oxygen may be observed. A muscle-*Kochsaff* similar to that used by Ahlgren has even less effect. If very high concentrations of cytochrome c are added to the bile solution there is a slow oxygen uptake. With the final preparation this is not observed.

It is of some interest to compare the contents of the original bile extract with those of the final product. In the former, in addition to the succinic dehydrogenase, the lactic dehydrogenase is present, but not the glycerophosphate enzyme which contact with bile salts destroys. Cytochrome oxidase and cytochromes a, b, c are present, though the spectra a and b are weak. Diaphorase (flavoprotein) is present. In the final preparation the lactic enzyme is not found, nor is the cytochrome oxidase. It contains some cytochrome c, but the spectra of a and b are not visible. Diaphorase is still present.

The striking difference between the glycerophosphate and the succinic enzymes is noteworthy, the latter being completely resistant to the action of

the bile salts. On the other hand, the lactic enzyme, while resistant to bile salts, is wholly destroyed by urea. This recalls the equally striking difference between these enzymes under the influence of glutathione (Hopkins and Morgan)².

The following table summarizes some typical results of our experiments.

30 mgm. dry weight of enzyme preparation, 0.3 ml. *M/2* succinate, pH = 7.0, temperature 37°.

Methylene blue (400 γ)	Reduction in minutes	Oxygen uptake (μl/30 min.)
1. Salt extr. heart muscle	5	1. Salt extr. heart muscle 230
2. Salt extr. heart muscle in presence of deoxycholate ..	12	2. Salt extr. heart muscle in presence of deoxycholate .. 170

Lactic Dehydrogenase and Cytochrome

THE bulk of the respiration of most animal tissues, yeast, etc., takes place through the alternate oxidation and reduction of cytochrome. The reduction of cytochrome is mainly due (a) to a small group of dehydrogenases which are believed to reduce cytochrome directly, and (b) to flavoproteins which transport hydrogen from other dehydrogenases through coenzymes I and II. A typical dehydrogenase of the first class is the lactic dehydrogenase of yeast, which does not depend upon these coenzymes or flavoprotein, but which in the crude state reduces cytochrome *c* readily in the presence of lactate. Some months ago we observed that a partially purified preparation of this dehydrogenase failed to reduce cytochrome, though it still reduced other hydrogen acceptors like methylene blue. We are at present engaged in the purification and isolation of this enzyme. We find that the purified enzyme still reduces methylene blue freely in the presence of lactate, but is completely inactive towards cytochrome. The following experiment shows this very clearly.

Absorption of oxygen was measured in Barcroft manometers in the usual way. Curve A shows the oxygen uptake of the purified lactic dehydrogenase + lactate + methylene blue: any methylene blue reduced is, of course, re-oxidized with uptake of oxygen. Curve B shows the uptake of the dehydrogenase + lactate + cytochrome *c* + cytochrome oxidase: had any cytochrome been reduced it would have been re-oxidized by the oxidase with uptake of oxygen. Curve C shows the uptake of *p*-phenylenediamine + cytochrome + cytochrome oxidase, showing the presence of an excess of oxidase, which was highly active in oxidizing cytochrome reduced by the *p*-phenylenediamine.

These results show that an additional catalyst is necessary for the reduction of cytochrome, possibly a hydrogen-carrier acting between the dehydrogenase and cytochrome. This is present in the crude preparations, but is removed in the purification process. We have shown that this catalyst is not identical with any of the known coenzymes, the flavoproteins of yeast or muscle, or the flavine mono- or di-nucleotides. It is of interest that Haas¹ finds that although

CURVE A: 1 c.c. LACTIC DEHYDROGENASE + 0.3 c.c. *M.* LACTATE + 0.1 c.c. *M/1,000* METHYLENE BLUE + 1.6 c.c. BUFFER.

CURVE B: 1 c.c. LACTIC DEHYDROGENASE + 0.3 c.c. LACTATE + 0.5 c.c. CYTOCHROME *c* + 1 c.c. CYTOCHROME OXIDASE + 0.2 c.c. BUFFER.

CURVE C: 0.2 c.c. *p*-PHENYLENEDIAMINE + 0.5 c.c. CYTOCHROME *c* + 1 c.c. CYTOCHROME OXIDASE + 1.3 c.c. BUFFER.

his flavoprotein reduces cytochrome, it loses this property when highly purified. It is possible that the same or a similar catalyst is involved. If this catalyst is necessary for the reduction of cytochrome, it follows that it must play a very important part in cell respiration.

A New Method of the Determination of Saturation by Vitamin C

THE only reliable method for determination of the saturation of the living body by vitamin C has so far been that of Tillmann-Harris-Ray. It consists essentially of the daily administration of 300 mgm. of ascorbic acid intravenously, until at least half of this amount reappears in the urine. If the body was saturated, the ejection of this quantity takes place within 1-4 days afterwards. If hypovitaminosis dominates, then the ejection is delayed. So far, by examining blood directly only extreme values can be evaluated: above 1 mgm. per cent indicates saturation, while below 0.4 mgm. per cent indicates hypovitaminosis. Concentrations ranging between cannot be evaluated properly, because

0.5 mgm. per cent may already signify saturation, while in contradistinction 0.9 mgm. per cent may, in certain circumstances, indicate hypovitaminosis.

It seemed probable that intravenous injection of 300 mgm. of ascorbic acid after a previous determination of the vitamin C concentration prevailing in blood may disclose, after repeated determination, whether saturation or hypovitaminosis was originally present. In the latter case, the amount of vitamin injected may be expected to make up the amount and the subsequent determination would disclose this fact by giving the same or an only slightly increased value compared with that of the first determination. If, on the other hand, saturation originally prevailed, the values of the second determination would disclose an increased amount, the organs storing the substance either slowly or not at all.

The validity of this assumption was proved experimentally. If the first determination disclosed less than 1 mgm. per cent concentration, and 300 mgm. were injected, at least double the amount was determined two hours afterwards, indicating that originally saturation dominated. If hypovitaminosis was originally prevalent, the ultimately determined amount was the same as the original, or slightly increased, but never twice as much.

In cases which displayed a concentration higher than 1 mgm. per cent from the start, this was not always doubled after the subsequent injection, the surplus being somehow ejected. In some cases it was possible to ascertain that the ejection was due to the renal function. The practicability of the test is not impaired by this since concentration above 1 mgm. per cent signifies saturation anyhow. All cases were controlled by the Tillmann-Harris-Ray test and the intracutaneous method of Rotter.

For determining the blood concentration, the method of Berend-Fischer was applied, this being sufficiently simple for clinical purposes. Out of forty cases investigated, only one proved a failure.

Free and Bound Vitamin B₁ in Milk

We have shown¹ that the fluorimetric assay² of vitamin B₁ in milk gives values about 50 per cent lower than the biological test. The difference was not due to the presence in milk of free cocarboxylase or of the monophosphate, as in no case could more than a trace of fluorescence due to oxidized phosphorylated anserin be observed in the aqueous layer after extraction with iso-butanol.

We now find that after incubation of raw milk or of reconstituted dried milk with taka-diastase (containing taka-phosphatase, protease and doubtless other enzymes) at pH 3.7-4.0, the fluorimetric assay is almost doubled. Peptic digestion gives very similar results even when the phosphatases of milk have been inactivated by heating.

It seems probable, therefore, that, in addition to free vitamin B₁ there is present in milk a vitamin B₁-protein complex. Ultra-filtration experiments support this view. After filtration of milk through 'Cellophane' the serum contains only free anserin and the substance which yields vitamin B₁ after incubation with pepsin or treatment with taka-

diastase is concentrated in the protein fraction. The recovery is nearly quantitative.

The evidence suggests that the bound vitamin B₁ is not adsorbed but is a constituent of the protein molecule.

Production of Diacetyl by Faecal Streptococci

In an investigation of the metabolism of both 'resting' and growing cells of lactic acid bacteria we have found that only the faecal streptococci (*Str. faecalis* and *Str. liquefaciens*) produce considerable quantities of diacetyl, which is recognized to be responsible for part of the aroma of milk products. No other lactic acid bacterium studied in this way produced diacetyl.

The bacteria in massive suspension were held in phosphate buffer plus glucose at pH 6.25, or grown in milk and yeast milk. Diacetyl was only produced in the presence of oxygen. Distillation with ferric chloride greatly increased the yield of diacetyl so that of the acetoin produced in the fermentation only a small part had been oxidized to diacetyl, which was identified by smell, the Voeges-Proskauer reaction and the formation of nickel dimethylglyoxime.

Aroma in butter and other milk products is usually attributed to the fermentation of citric acid by the citric fermenting streptococci¹ and it has also been claimed that the heterofermentative lactobacilli can produce the aroma substances². It may be emphasized that both these groups are quite unable to form the aroma compounds from glucose under 'metabolic' conditions.

PRODUCTION OF AROMA CONSTITUENTS UNDER ANAEROBIC CONDITIONS

	"Metabolic" tests (Washed cells in glucose-phosphate)		Cultural tests (Growing bacteria in milk and yeast milk)	
	<i>Str. faecalis</i>	Heterofermentative streptococci and lactobacilli	<i>Str. faecalis</i>	Heterofermentative streptococci and lactobacilli
Volatile acid	+	+	0	+
Alcohol	0	0	0	+
Diacetyl + acetoin	+	0-	+	0

It is well recognized that milk produced in a very clean manner yields a mild flavoured cheese and that the best and fullest flavoured cheese are frequently made under conditions favouring the seeding of the milk with many organisms, of which the faecal streptococci may be directly concerned in the production of flavour.

Quantitative Inhibition of Oestrone by Progesterone in the Baboon, with Reference to this Phenomenon in other Animals

THE object of this preliminary note is to direct attention to the remarkable variation existing in different species of mammals in their sensitivity to the action of the ovarian hormones.

Experiments have been performed on the prepubertal baboon (*Papio porcarius*) and the size of the perineum has been used as an indicator of activity since the variations of the perineal swelling during the menstrual cycle have been shown to be as useful an indicator as the vaginal smear method¹.

A, 10 daily injections of oestradiol;
B, 11 daily injections of oestradiol and progesterone.

GRAPHS ILLUSTRATING THE DIFFERENT EFFECTS PRODUCED BY 1 MGm. AND 2 MGm. PROGESTERONE GIVEN SIMULTANEOUSLY WITH OESTRADIOL IN THE SAME IMMATURE BABOON.

- 1 mgm. oestradiol benzoate injected daily for 10 days, followed by the simultaneous injection of 1 mgm. oestradiol benzoate and 1 mgm. progesterone daily for 11 days. Note the incomplete deturgescence and absence of bleeding within 96 hours.
- 1 mgm. oestradiol benzoate injected daily for 10 days, followed by the simultaneous injection of 1 mgm. oestradiol benzoate and 2 mgm. progesterone daily for 11 days. Note complete deturgescence and bleeding within 96 hours.

Prepubertal baboons were first given 1 mgm. oestradiol benzoate for 10 days to produce perineal turgescence and then given simultaneous daily doses of 1 mgm. oestradiol benzoate together with varying amounts of progesterone. When 1 and 2 mgm. progesterone are administered under these conditions the induced perineal turgescence rapidly disappears and the perineum returns to rest. Bleeding follows within 60-90 hours after the last injection. When, however, only 1 mgm. progesterone is injected together with 1 mgm. oestradiol benzoate, the deturgescence is much slower, and bleeding does not occur within 96 hours after the last injection, as shown in the accompanying graphs. On this basis we conclude that 1 mgm. progesterone is just insufficient to inhibit the action of 1 mgm. oestradiol benzoate on the perineum of the baboon, whereas 2 mgm. progesterone completely inhibits 1 mgm. oestradiol benzoate.

It is important to compare our findings with those of other investigators who used methods similar to our method on other animals which, however, were castrated.

(a) Robson², in the mouse, found that 750 μ gm. progesterone was required to induce an inhibitory effect on 0.2 μ gm. oestrone (that is, 3,750 progesterone: 1 oestrone by weight). In the rabbit, however, Robson³ found that the effect of 0.75 μ gm. progesterone could be completely inhibited by 0.01 μ gm. oestrone (that is, 75 progesterone: 1 oestrone by weight). These results indicate that the rabbit is fifty times more sensitive to progesterone than the mouse.

(b) Leonard, Hisaw and Fevold⁴ found that in rabbits castrated during oestrus 10 R.U. oestrone seemed to be the smallest quantity required to prevent the action of 1 Rabbit Unit 'corporin'. In the monkey, on the other hand, Hisaw⁵ discovered that $\frac{1}{2}$ Rb.U. 'corporin' is at least partially effective in counteracting 100 R.U. oestrone. These experiments indicate that the monkey is twenty times more sensitive to progesterone than the rabbit.

(c) Our own experiments indicate that 2 mgm. progesterone is completely effective in inhibiting the action of 1 mgm. oestradiol benzoate on the perineum of the baboon (that is, 2 progesterone: 1 oestradiol benzoate by weight). Robson², using oestradiol in the mouse, found that 750 μ gm. progesterone were required to induce an inhibitory effect on 0.05 μ gm. oestradiol (that is, 15,000 progesterone: 1 oestradiol by weight). These findings suggest that the baboon is about 7,500 times more sensitive to progesterone than the mouse.

From the above homologies (a), (b), (c), we may express mathematically the sensitivity to the action of progesterone of the various animals discussed as follows:

baboon: monkey: rabbit: mouse :: 7500: 1000: 50: 1.

It is suggested that as we ascend the phylogenetic scale in the animal kingdom there is an increasing sensitivity to the action of progesterone, and it is possible that in the human female an even greater sensitivity to the action of progesterone may exist.

Transmutations of Uranium and Thorium Nuclei by Neutrons

WE have recently bombarded layers of uranium oxide and thorium oxide with a mixture of fast and slow neutrons and investigated chemically the active substances obtained on glass plates about 1 mm. away. These active bodies, which result from the bursting of the particular nucleus¹, were dissolved off for analysis with aqua regia, tests showing that no comparable activities came from the glass itself.

In the case of uranium we have been able to assign half-lives of 86 min. to barium, 4 hr. and 40 hr. to lanthanum and 16 min., 75 min. and 72-76 hr. to elements of the 'trans-uranium' type (precipitated

with platinum as carrier from 2*N* hydrochloric acid solution with hydrogen sulphide). We consider the appearance of the 16 min. and 72-76 hr. activities (presumably identical with Hahn, Meitner and Strassmann's¹ 16 min. eka-rhenium and 66 hr. eka-iridium) on the glass plate to be conclusive proof that these substances must be due to recoiling fragments of the bursting uranium nucleus, and that they are not 'trans-uranium' elements coming from uranium by a chain of β -processes.

We have been looking also for possible 'trans-uranium' elements resulting from the decay of uranium (23 min.), which is certainly a uranium isotope. Some weak activities which have some of the properties of 'trans-uranium' elements have been found. More rigorous tests are in progress, however, to make their identity certain.

The activities which are obtained by recoil on the glass plates when thorium is bombarded have also been studied. As a great number of periods were observed, we have for the present classified only some of them into groups according to their chemical behaviour. We found, for example, bodies of 80 min., 14 hr. and 12 days half-lives with the properties of rare earths (lanthanum carrier), 6 hr. with those of barium, 70 min., $4\frac{1}{2}$ days and about 11 hr. (which latter appears to grow from the $4\frac{1}{2}$ -day body) with the properties of noble metals. Blank tests showed that thorium B and thorium C activities were negligible.

In addition, from samples of specially purified thorium nitrate irradiated in bulk, activities of $2\frac{1}{2}$ hr. and 22 hr. were extracted which had the properties of bromine. Since the $2\frac{1}{2}$ hr. period has been assigned² to ⁸²Br, it is natural to identify this with our $2\frac{1}{2}$ hr. period. Two weak selenium activities (some hours and some days) were also observed.

These experiments were possible only through the kind collaboration of the High Tension Laboratory staff, who provided the neutron sources (lithium + deuteron). We are also indebted to Dr. R. S. Krishnan for his aid in taking readings with the counter set.

Liquefaction of Helium

ON March 7, we succeeded in liquefying helium by using an apparatus based on the Simon expansion principle. We obtained with one expansion, starting from a pressure of 80 atm. and a temperature of 14.6° K., a quantity of about 65 c.c. of liquid helium. The maximum capacity of our apparatus is about 120 c.c. It was also possible to lower the temperature to 3.3° K., by reducing the pressure above the helium.

We made also one expansion starting from a pressure of 30 atm. and a temperature of 24° K., and we arrived at a temperature of 11° K.

It is worth pointing out that the time which is necessary to obtain liquid helium by this method is relatively short. On March 7 we obtained helium in 6 hours. On March 14 we repeated the experiment, and then only 4 hours was required to obtain liquid

helium. It will no doubt be possible to reduce this time to only 3 hours. In this time is also reckoned the time which is necessary to liquefy the hydrogen used for this experiment.

During these experiments I was assisted by M. van Dingenen and M. A. Werner.

Effect of Foreign Gases on the Continuous Absorption Spectrum of Bromine

ALTHOUGH much attention has been devoted to the broadening of spectral lines in the presence of foreign gases, little systematic work has been done on the effect of foreign gases on intensities of absorption spectra. We have therefore examined the effect of the following gases on the continuous absorption of bromine, using an objective method of photographic photometry: hydrogen chloride and bromide, carbon dioxide, oxygen and nitrogen.

With bromine and the foreign gas at partial pressures of 2 cm. and 60 cm. respectively, the effect is to increase the intensity of the main absorption continuum ($\lambda_{\text{max.}} = 4150 \text{ \AA.}$) without altering the general shape of the absorption curve. The *A* and *B* components of this 'continuum' are affected about equally, and there is practically no shift in the position of the maximum. The table of absorption coefficients at the maximum serves to show the magnitude of the effect.

Gas	Bromine alone	Bromine plus 60 cm. of				
		HCl	CO ₂	HBr	O ₂	N ₂
<i>K_{max.}</i>	152	191	184	182	167	163

Experiments with varying partial pressures of hydrogen chloride and carbon dioxide indicate that the increase in intensity is proportional to the partial pressure of the foreign gas.

The ultra-violet absorption continuum of bromine between 3300 $\text{\AA.}$ and 2500 $\text{\AA.}$ ² is affected to a much greater extent, the intensity being increased as much as ten-fold by 60 cm. of hydrogen chloride or bromide. In this region, numerical values of the absorption coefficient may have little meaning, since in the presence of oxygen they are not independent of the partial pressure of bromine.

Theory of Mesons and Nuclear Forces

IN a recent note¹ on the static interaction between nuclear particles, Dr. C. Møller and Prof. L. Rosenfeld describe the results of a canonical transformation which makes it possible to separate dynamic and static interactions, and they state: "The static interaction is in all cases exactly the same as that obtained as a first approximation in the perturbation method". They referred to certain work done previously² by

me, and I wish to point out that the above statement does not correspond to my results. If this statement applies to the interaction between two Dirac electrons, this is only because in that case we have but *one component* of the field giving static effect, namely, the electrostatic potential. For nuclear interactions, the field must have at least *two components* (usually expressed as one complex field: the meson field). If one tries as before to separate each component into the static solution of the wave equation and the transformed field component, one finds that this transformation is no longer canonical. This is due to the fact that these static parts do not commute because they are formed with the aid of the non-commuting 'isotopic spin matrices' of the heavy particles.

However, canonical transformations exist, which separate a static part of the field (different from the static solution of the wave equation). These transformations introduce a static interaction, which is *not the same* as the one obtained as a first approximation in the perturbation method. Its exact form will be discussed elsewhere, but we can state that, expressed as a power series, its first term corresponds to the first approximation in the perturbation method.

The equations for the transformed fields (pure radiation fields) are, in the static approximation, obviously satisfied by the particular solution: transformed fields equal to zero. (The term "static approximation" means that all effects due to *particle velocity* have been neglected.) However, if these fields are considered as quantum mechanical variables, it is known that their squares can never be zero (zero point energy of the radiation field). This fact leads to an additional, also purely static, displacement of the nuclear energy levels proportional to Planck's constant $\hbar$.

Growth of the Large-mouth Black Bass, *Huro salmoides*, in Lake Naivasha, Kenya

RECENTLY, measurements and samples of scales from twenty large-mouth black bass caught in Lake Naivasha were received from Dr. Richard H. Le Pelley, of the Scott Agricultural Laboratories, Nairobi, Kenya. The sizes of these fish are about the same as are taken in good bass-fishing lakes in the Mississippi valley. Although the temperature range of Lake Naivasha is very small, the scales of these fish have annual rings much as in bass taken in temperate regions. The ages of these twenty bass have been read as follows:

Age (years)	Weight	Total length (inches)	Age (years)	Weight	Total length (inches)
4	2 lb. 8 oz.	17	2	2 lb. 0 oz.	14
3	2	15	2	1 14	14
3	2 0	15	2	1 6	14
3	1 14	15	2	1 8	13
3	2	13	2	1 4	13
2	3 4	17	2	0 12	12
2	3 4	17	1	0 8	11
2	2 0	15	1	0 7	10
2	1 14	15	1	0 8	9
2	1 8	15	1	0 7	9

Excerpts from Dr. Le Pelley's letter give the essential facts about this bass population and Lake Naivasha.

"As far as I can find out, the following information on the introduction of this fish to Kenya is accurate. The young fry were obtained from somewhere in Europe where the introduction [from America] had been made previously. Nearly all died on the journey, but the remainder, about fifty-three young black bass about three inches long, were loosed in Lake Naivasha in February, 1929. They flourished and bred, and fishing began in October, 1931. The fish is plentiful to-day. Previous to 1925 the only fish in the lake was a minnow-like fish *Haplochilus antinorii*. In 1925 *Tilapia nigra* was introduced and this multiplied enormously. Both these species, as well as frogs and other animals, form the food of the bass. The largest black bass recorded, taken from Naivasha in 1937, was 6½ pounds.

"Lake Naivasha lies at an altitude of about 6200 feet; is about 100 square miles in area; approximate position 36° E. longitude, 1° S. latitude; 15 metres deep, temperature 62° F., with probably a very small range only.

"Black bass have also been introduced into one of our rivers—the Athi River, where they appear to be established."

An average growth curve has been computed from measurements of the distances between annuli along the anterior radii of the scales. For comparison, growth curves for large-mouth bass in Horseshoe Lake¹ in southern Illinois, and for the lakes of Wisconsin², are included. In the Illinois lake, the first year of growth was unusually rapid, as the result of abundant animal food for young bass and lack of competition with other carnivorous fishes. In the Wisconsin lakes, the growing season for bass is about half that of Horseshoe. These northern lakes have ample food for the larger sizes; but fingerlings find food scarce and competition with other species keen.

The Naivasha bass averaged 14 per cent heavier than bass of the same lengths from a population which is regarded as normal for Illinois, and the bass of the latter, in turn, are heavier than Wisconsin bass of the same lengths.

In Illinois, most large-mouth bass form their annuli in May and June, and it has been of interest to find out when they form their annuli in a lake so near

the equator with a very small temperature range (Illinois bass tolerate 32°F. to 90°F.). In no case did the Naivasha scales show an annulus near the edge. The amount of scale-growth outside the last annulus averaged 97 per cent of the corresponding whole year's growth in the scales of older fishes. Since these scales were collected on March 17, it would seem to indicate that annuli would be formed very soon—probably in April. It may be expected that they also spawn at this time, since spawning and annulus formation are known to occur at about the same time.

Course of Pollen Tube Growth in *Carica papaya* and *Cucurbita* spp.

In a recent paper, Gustafson¹ states with reference to pumpkin and crookneck summer-squash (*Oucurbita* spp.) that the "application of pollen to one side of the ovary did not limit the development of the seeds to that side, and the seed distribution was quite uniform even when as much as five-sixths of the stigma had been removed. . . . It was expected, however, that the seeds might develop only on that side of the ovary where the pollen was applied and the side without seeds would be apertrophied". Work on the course of pollen tube growth in *Carica papaya*, carried on by us in Florida in 1936 as part of a Bankhead-Jones project, has a bearing on this subject. The Caricaceae are related not distantly to the Cucurbitaceae, but the former have superior ovaries in contrast to inferior ovaries in the latter. However, the general place of entry of the pollen tubes in relation to the extent and display of the placental surface is similar.

The paraffin embedding method was used in this work, and the pollen tubes were stained with acid fuchsin to which light green was added according to the formula of Buchholz. In *Carica papaya*, the pollen tubes grow from the stigma through the central region of the style to the apical end of the ovarian cavity, and then emerge into, and grow on, the surface of the ovarian cavity to the ovules. The ovarian cavity is relatively large (approximately 18 mm. long in the material used), and under the conditions of the experiment it took about five days for the pollen tubes to reach the ovules at the proximal end, although the ovules at the apical end were reached in about one and a half days. Since the tubes enter the ovarian cavity directly at the centre at the apical end, it would make no difference from which part of the stigma the tubes started, and the direction of growth after entering the ovoid or rounded cavity, other things being equal, would be dependent on chance alone. If sufficient viable pollen is applied to any part of the stigma, the thousand ovules (more or less) in the ovarian cavity may all be fertilized, unless some such condition as incompatibility or difference in state of receptivity intervened. If insufficient viable pollen is applied, then the ovules in any region equidistant from the apical end of the cavity will have an equal chance

of being fertilized so long as there remain a sufficient number of pollen tubes. This would explain the uniform seed distribution in the fruits of *Cucurbita* spp. even if pollen was applied to one side of the stigma only.

The complete results will be published in the *Journal of Agricultural Research*.

Ferrous Iron in Soils

THERE has been a controversy in the literature concerning ferrous iron in soils on three points, namely: (1) Is ferrous iron present in large quantities in ordinary healthy soils? (2) Can soil fix iron in the divalent form? (3) Does the downward movement of iron in soils, such as the podsoles, take place in the ferrous condition?

The details of the experiments undertaken to elucidate the problems outlined will be given elsewhere. In this communication merely the results and conclusions are presented. In all the work reported the ferrous iron was determined by the dipyriddy method¹, and the experiments were conducted on black chernozem and grey wooded podsol soils.

To study the formation of ferrous iron and its downward movement black and podsol loams were kept submerged under distilled water in percolators. During the first twenty-six days of the experiment no ferrous iron was found in the percolates. After the experiment had continued for sixty-five days small quantities of ferrous iron were found in some of the percolates, ranging from 9-27 gamma in the volumes of liquid collected during twenty-two hours. Only traces of ferrous iron were found in water extracts of portions of soil taken from the percolators.

The same portions of soil were then extracted with approximately 3 per cent solution of aluminium chloride. An average of 750 gamma of ferrous iron was extracted from 1 gm. of black loam and 425 gamma from 1 gm. of the podsol loam, these figures being given on the basis of oven-dried soil.

This experiment indicates that soils must be water-logged for a considerable period of time before iron moves in the ferrous state, and that certain soils, at least, can hold a considerable amount of iron in the divalent form, which is not easily removed by water, but can be extracted by aluminium chloride solution. Approximately 75 per cent more ferrous iron was extracted from the black soil than from the podsol soil, indicating that the presence of organic matter under anaerobic conditions encourages formation of ferrous iron.

In another experiment it was shown that from a solution of ferrous chloride approximately 1,600 gamma of ferrous iron were absorbed by 1 gm. of moist black loam, and 1,300 gamma by 1 gm. of moist podsol loam, within a two-hour period, the black loam absorbing all the iron supplied. After a twenty-four hour interval 10.56 N solutions of

potassium chloride, ammonium chloride and aluminium chloride released respectively 12 per cent, 15 per cent. and 26 per cent. of the ferrous iron absorbed by the podsol loam. In the case of black loam aluminium chloride solution released 8 per cent of the ferrous iron absorbed. The black loam absorbed more ferrous iron than the podsol loam, and the iron was retained more efficiently by the former than the latter. A part of the iron absorbed by these soils may have reverted to the trivalent insoluble form, as was suggested by Wilkoszewski², but a certain amount of iron remained in ferrous condition and was probably held in the base exchange complex.

The extraction of ferrous iron with potassium chloride, ammonium chloride and aluminium chloride solutions from samples of podsol loam in which formation of ferrous iron had been induced gave similar results. In this case pH values of the extracting solutions in contact with the soil were determined because the hydrogen ion concentration of these may have influenced the extraction of iron from the soil.

pH of water	..	7.4
pH of KCl solution	..	6.18
pH of NH ₄ Cl	..	5.92
pH of AlCl ₃	..	2.92

From these results one may assume that ammonium and potassium displace the ferrous iron from the base exchange complex. Aluminium chloride solution, which is the best of the extracting agents used, may extract the iron from soil in two ways: by virtue of its high acidity and by displacement of ferrous iron by the aluminium cation.

Three per cent aluminium chloride solution extracts of soil surface (0-8 in.) and subsurface (12-18 in.) samples taken at widely divergent points showed, in the case of black soils, no ferrous iron or only traces; but in the case of podsol soils generally a little more, the figures ranging from traces to about seven parts per million for the surface samples and from traces to twelve parts per million for sub-surface samples, on the basis of oven-dried soil.

These figures show that only very small quantities of ferrous iron could be extracted from these soils. From the percolation and field experiments reported in this communication it may be suggested that the reduction of iron in soil has not been a major cause of downward movement of this element in podsol soils.¹

"Animal Treasure"

In a review of my book "Animal Treasure" which appeared in NATURE on April 23, 1938, there occurred the passage "some of the statements have been seriously challenged by Mr. Arthur Loveridge in the *Scientific Monthly* of January 1938". I have just returned from a year's collecting trip to Surinam and have only recently seen both the review and the original criticisms mentioned.

I propose submitting a detailed reply to Mr. Loveridge's article in *Scientific Monthly* to the editor of that journal with the view of publication. There Mr. Loveridge made twenty criticisms in numbered paragraphs to prove that "Animal Treasure" was "to so large an extent a compound of misstatement, misinterpretation, exaggeration, sentimentalism and emotionalism". Since I am replying to Mr. Loveridge in detail elsewhere, I shall mention only a few points here. I feel, however, impelled to bring this to the notice of readers of NATURE, since Loveridge's article was mentioned in the NATURE review, and his criticisms have received widespread attention.

Perhaps the most important of Mr. Loveridge's criticisms is that I have blundered when he quotes from my book that: "We captured six diurnal animals in Africa that belonged to groups all the other members of which are exclusively nocturnal. All six animals—a snake (*Gastrophyscus senecagadina*), a squirrel (*Furiscivorus pansis*), a monkey (*Cerco-pithecus pogonias*), a rat (*Demomys hypoxanthus*), a flying squirrel (*Anomalurus beccrofti*) and, finally, a lemur (*Galago demidovii*)—were bright green above and yellow beneath, whereas their near-related and nocturnal species were all of other colours" (p. 167). He states that the snake, squirrel and monkey belong to diurnal groups and none of the animals conform to my description except the snake, and "by courtesy" the squirrel. I regret the necessity of correcting Mr. Loveridge in these observations as all the animals referred to are bright greenish above and yellow below¹. They still show the full yellow in the preserved specimens at the British Museum. The dorsal coloration has faded (as green always does) to olive or misty-grey-olive. Mr. Loveridge states that the pelage of mammals undergoes 'no radical changes on preservation beyond a slight dulling and fading with the passage of time, but here again I would point out that the reaction to which I have referred is, contrary to the view of Mr. Loveridge, well known to museum workers, furriers, etc.

Mr. Loveridge also states that I cannot even copy accurately from other authors. In "Animal Treasure" I referred (without quoting) to Mr. G. L. Bates as having found a male *Nectophryne batesii* sitting on a brood of eggs. Quoting from Dr. G. A. Boulenger, Mr. Loveridge claimed that Mr. Bates had found a female *N. batesii* with empty oviducts under the trough or hollow of a plantain-leaf petiole crouched in the midst of a mass of eggs. I accept Mr. Loveridge's quotation²; Dr. Boulenger's description is from Mr. Bates's original field notes. I had cause to examine this specimen, which is in the British Museum, and it proved to be a male as stated by Mr. H. W. Parker³, assistant keeper in the British Museum (Natural History). Further, Mr. Loveridge's statement that the eggs were "beneath the base of a banana leaf apparently lying on the ground" is incorrect; a plantain-leaf petiole is customarily several feet from the ground.

"Animal Treasure" has never been claimed by me to be a purely scientific work, but as a popular introduction to the public of some of the wild life of West Africa.

All Mr. Loveridge's other criticisms, whether purely scientific or vaguely censorious, can be, and are being, refuted in like manner. It therefore seems necessary to point out that his judication rests merely upon his own opinions at present.

Full details of the actual scientific results will be found in the publications listed below^{4,5,6,7,8}.

A large work on the 1,500 mammals, with coloured plates of several species (notably the green and yellow monkey) and full details of all controversial points raised above is in the Press and shortly appearing as a volume of the *Transactions of the Zoological Society of London* (24). The reptiles, Mollusca, Myriapoda and certain arachnid groups are not yet worked out in full.

Foam on the Dead Sea—and off the Mæander River

A FOAM-FORMATION like that described in *NATURE* of March 15, p. 468, is to be seen off the mouth of the Mæander (*Mendere*) River in western Asia Minor,

when the river is in flood. The turbid river water establishes a sharp frontier with the clear sea-water, and when the breeze is on-shore, the sea-water *breaks* on the river water with sufficient force to accumulate a band of foam, several inches wide, which in turn retains scum and floating debris from the river. The foam band is carried by wind and current into arc-forms, which are the more conspicuous by reason of the contrast of water-colour within and without. For the salt and fresh waters do not readily mix, and the summary deposition of the silt at the point where the flood water is checked probably explains the very steep gradient of the delta escarpment.

Checked in front, the flood water escapes along-shore and retains its café-au-lait hue for many miles. I have encountered it south of the channel between Kos and Kavø-Krio (fifty miles), and west of Nikaria Island (sixty miles), according to the direction of the wind and resulting 'wind-rip' current. When the wind is between south-east and south-west, in the Ægean, the water is piled up to the north, and escapes by inshore channels; when the wind is in the north, the water is driven south, and is replaced by northerly currents inshore. Best known of these inshore currents is the famous and incalculable '*Gephyra*', between Eubœa and the mainland of Greece.

New College,
Oxford.

JOHN L. MYRES.

Points from Foregoing Letters

PREPARATIONS of the succinic dehydrogenase are described by Sir F. Gowland Hopkins, C. Lutwak-Mann and E. J. Morgan which, while very active in reducing methylene blue, fail completely to induce an oxygen uptake in a system containing succinates, cytochrome c and cytochrome oxidase. It is clear, therefore, that some factor is necessary for transferring the hydrogen atoms activated by the enzymes to the cytochrome system.

M. Dixon and L. G. Zervas state that cytochrome c is not reduced by the purified lactic dehydrogenase system of yeast, but that an additional intermediary catalyst is necessary and that this may play an important part in cell-respiration.

C-hypovitaminosis can be recognized by blood-test, by determining the concentration of the vitamin in serum, before and after the intravenous injection of 300 mgm. of ascorbic acid. According to A. Göth, in case of saturation, the value determined after two hours should be at least twice that previously found; if less, hypovitaminosis dominates.

J. Houston and S. K. Kon find that, in addition to free vitamin B₁, milk contains the substance also in a bound form, most probably as a vitamin B₁-protein complex.

Of many types of lactic acid bacteria studied by J. G. Davis, H. J. Rogers and C. O. Thiel, only *Str. faecalis* and *Str. liquefaciens* invariably produced diacetyl from glucose, both under "resting" and under growing conditions. This finding is discussed in relation to the production of flavour in milk products.

Experiments indicating that progesterone has a greater ability of inhibiting the action of œstrone in the higher animals (baboon, monkey) than in lower animals (rabbit, mouse) are described by J. Gillman and H. B. Stein.

By analysis of the recoiling fragments of exploding uranium nuclei, E. Bretscher and L. G. Cook find that the existence of true 'trans-uranium' elements cannot generally be maintained. Results of observations on disintegration of thorium by neutrons are also given.

N. S. Bayliss and A. L. G. Rees find that the addition of foreign gases to bromine increases the intensity of the main bromine continuum by amounts from 7 per cent in the case of nitrogen to 25 per cent in the case of hydrogen chloride. The ultra-violet absorption of bromine is increased as much as ten-fold.

Defining *static interaction between particles* as the value of the interaction energy for zero particle velocity, E. C. G. Stueckelberg shows that for nuclear interaction its form is different from the static solution of the wave equation of the meson field.

Data submitted by D. H. Thompson show that the large-mouth black bass, *Huro salmoides*, introduced since 1929 in Lake Naivasha, Kenya, grows faster and is heavier than specimens of the same length in Illinois.

H. P. Traub and C. T. O'Rork, jun., find that pollen tubes enter the ovarian cavity of *Carica papaya* directly at the centre at the apical end, no matter which part of the stigma they started from. This explains the uniform distribution of the seeds in this and related families (Cucurbitaceae).

Small amounts of ferrous iron (of the order of 0.1 per cent) have been extracted by V. Ignatieff from certain soils (black loam and podsol loam) which have been waterlogged for more than two months.

J. L. Myres points out that foam-formation like that described in *NATURE* of March 15, p. 468, in the Dead Sea occurs off the Mæander River in western Asia Minor, and is due to the breaking of the sea-water on the river water when the wind is on-shore.

Research Items

Excavations at Chametla, Sinaloa

IN a report on three weeks' excavation in the vicinity of Chametla in the southern part of the State of Sinaloa, Miss Isabel T. Kelly describes a pioneer investigation which was undertaken under the auspices of the Institute of Social Sciences on behalf of the University of California (*Ibero-Americana*, 14, 1938, Univ. California Press). Chametla lies on the Baluarte River, some kilometres down stream from Rosario. The modern unimportant village occupies a site which, according to contemporary accounts, was once the centre of a native State of some importance. It is to be assumed that the pre-white economy was purely agricultural. The valley abounds in low mounds, which mark former dwelling sites. There are also several large artificial mounds; but these were not examined. No architectural remains were found, though Oviedo reports adobe structures. There was no sign of metal, except a smooth disk, possibly a post-conquest copper coin. Axes, manoes and chipped obsidian occurred; but the material was overwhelmingly ceramic. This pottery is of considerable intrinsic interest, excellent in quality and diversified in character—especially in view of its marginal location. The fundamental wares are a red-rimmed utility and black-banded wares, which persist through a succession of polychrome styles. In a tentative chronology the early occurrence of Chametla polychrome is well defined, while among later decorated wares, though distinct varieties are much confused, certain complexes with chronological significance appear to emerge. Apparently the succession does not endure down to conquest times. Even more surprising than its richness is the fact that this pottery is unique, and has no resemblance, generic or specific, to any known wares of other cultures. As to its provenance, having no affinities with Sonora to the north, nor the plateau on the east, while the Pacific lies to the west, the southern and coastal area alone remains. It would appear to be a spur of high culture along the coast, originating ultimately in Central America. But both the Chametla valley and the Pacific coast are at present *terra incognita*.

Anatomical Features of Fossil Skulls

SIR ARTHUR KNITH has re-examined the anatomical features of the Piltdown skull and of the Swanscombe skull (*J. Anat.*, Jan. 1939). This is Part 2 and the concluding portion of a very careful and detailed analysis. The Piltdown skull reveals several simian characters that had been previously overlooked, and it exhibits a degree of asymmetry not equalled in modern man. The recognition of this asymmetry allows of a more satisfactory reconstruction being made. Its cranial capacity is now estimated at 1368 c.c. The author concludes that the Swanscombe, the Piltdown, London and Bury St. Edmunds skulls represent a related group which may be termed the Piltdown group and so far it has only been found in England. They are of a different group from that of Neanderthal man. Swanscombe man is older than Neanderthal man, unless the Heidelberg jaw is to be regarded as representing a Neanderthal type. Thus in early Pleistocene times the Pithecanthrop and

Sinanthropic type was evolving in the east while the totally different Piltdown type was being evolved in the west. This latter general type continued into the mid-Pleistocene.

Distribution of Antibody in Tissues

C. F. Wang and H. Wu (*Chinese J. Physiol.*, 13, 429; 1938) have studied the antibody content of the different tissues of rabbits immunized with egg-albumin and have come to the following conclusions: (1) The maximum antibody content was found to be in the blood and in the tissues in the fifth to seventh week of immunization. (2) All the antibody could be removed from the tissue by perfusion. (3) The distribution of antibody in the tissues was in the following decreasing order: lungs, bone-marrow, kidneys, spleen, heart and liver. (4) Antibody was sometimes found in the uterus and testes. (5) No appreciable amount of antibody could be found in the stomach, brain or skeletal muscles. These findings are in harmony with the view that the antibody is formed in the organs of the reticulo-endothelial system.

Acrodynia and Fatty Acids

F. W. Quackenbush, B. R. Platz and H. Steenbock (*J. Nutrition*, 17, 115; 1939) found that on a basal diet of purified casein, glucose and salts, supplemented with carotene, calciferol, synthetic B₁ and riboflavin, rats developed skin lesions in 4-5 weeks; an acute dermatitis when restricted to the basal diet, and a chronic form, "rat acrodynia", when given fat supplements at subcurative levels. Complete healing of either the acute or chronic form was obtained by the administration of peanut oil or wheat-germ oil. Cured animals remained free from all symptoms while the fat supplements were continued or until the end of the survival period, which was usually several months. Aeration or ultra-violet radiations did not destroy the activity in peanut oil. It was resident in the fatty acid fraction. Cures were produced with half a drop of wheat-germ oil, corn oil or Wesson oil, 10 drops of coconut oil or 25 drops of butter fat. The lesions were not prevented or cured with hydrogenated coconut oil.

Polygamous Weavers

R. E. and W. M. Moreau continue their valuable studies of the ecology of African birds by observations on the comparative habits of two weaver birds, *Huplectes nigroventris*, the Zanzibar red bishop, and *H. horreacea*, the crimson-crowned bishop (*J. Anim. Ecol.*, 7, 314; 1938). Both birds have breeding seasons shorter than the vegetation growth would allow, but the former already has young when temperatures are at their highest and continues to breed through the 'long rains' until the middle of the cool season, whereas the latter breeds only at the coolest months of the year. In neither species does the size or position of the breeding territory bear any relation to availability of food of adults or young nor has it regular topographical features, yet while the red bishop occupies constantly a relatively large territory (900 ± 300 sq. yd.), the

crimson-crowned territory may be compressed to under 10 sq. yd. Notwithstanding this relative divergence in spatial occupation, a male of the last named in its small kingdom has up to five breeding females active in it at the same time and raising up to eight clutches in a season, although the red bishop has never been found to have more than three wives in his large territory. Indeed, in the breeding population of both species females are in the ascendant, outnumbering males by quite four to one, and the authors are endeavouring to discover whether this curious disparity is due to differential birth rate or to subsequent mortality.

Birds of Canton Island

CANTON ISLAND, one of the Phoenix Islands, is a low-lying coral atoll, 7 miles long by 4 miles broad, lying in a rainless belt 1,100 miles north-north-east of Fiji. Its birds were studied in 1889, and now again, in 1937, a second survey has been made, by Major G. A. Buddle (*Records Auckland Inst. Mus.*, 2, 125; 1938). The survey shows few changes in close on half a century, as perhaps was to be expected on an island undisturbed by human visitors, and occupied only by sea-birds and passing migrants. Twenty species of birds are recorded. The wideawake terns described as breeding in large numbers in 1889 have completely disappeared, but terns are a fickle people. Neither the migratory turnstone nor sandpiper noted in 1889 was seen, but a new visitor was recorded in *Fregata magnificens*. Major Buddle's observations were made from May 27 to June 8, 1937, during the visit of the New Zealand Total Solar Eclipse Expedition. Since then the British and American Governments have interested themselves in Canton Island as a probable air-base, and it is now permanently occupied by representatives of both peoples. Its bird life is likely to be considerably modified in the next fifty years.

Advances in Indian Helminthology

SIX contributions to Indian helminthology have recently been made by Dr. Har Dayal Srivastava (*Indian J. Vet. Sci. and Animal Husbandry*, Dec. 1938). Two of them deal with amphistomes found in Indian food fishes and two new genera and another new species are described. One is an account of a new species of alveocolid from *Chiloscyllium indicum*. Another describes a new gorgoderid trematode from *Balone strongylura*. The fifth is a study of the gastrostomatous parasites of Indian food fishes, and includes a key of the members of the genus *Bucephalus*; three species are here described for the first time. A new species of *Bucephalopsis* and two new species of *Proserhynchus* are also described as well as additional details of other species of the former genus. The last paper is a study of the life-history, pathogenicity and biological control of *Cotylophorum cotylophorum*, an important schistosome carried by the snail *Indoplanorbis exustus*.

Nitrogen Content of Apple Trees

J. E. KIRCH (*J. Pom. and Hort. Sci.*, 16, 346; 1939) has investigated the content of nitrogenous materials in the terminal shoots of Lane's Prince Albert apple trees as affected by the five rootstocks *M II*, *M V*, *M VII*, *M IX*, and *M B*. The data show that the nitrogenous fractions in bark and wood were strikingly similar for all five rootstocks, and

the variation from month to month did not differ significantly between stocks. The total nitrogen in the woody portions of the shoots, however, was higher for *M IX* than for the other stocks, which did not differ significantly from each other. Stock *M IX* seems to be associated with high amide content in the scion, especially in the young shoots, high asparagin content apparently being characteristic of this stock. The carbohydrate content of trees on *M IX* is also high relative to other stocks, and the carbohydrate/nitrogen ratios do not therefore differ appreciably. The seasonal cycles of the nitrogen fractions and C/N ratios are given and it is concluded that the chemical data, so far as terminal shoots are concerned, do not reflect the pomological differences between stocks. *M IX* alone induces any significant change in the chemical composition of the shoots of long-established trees.

Anatomical Manifestations of a Virus Disease

THE first macroscopical symptom of many virus diseases is a clearing or yellowing of the veins of a host plant; but later, the green parts of a mosaic-mottled leaf may run along some of the larger veinlets. Miss F. M. L. Sheffield, of Rothamsted Experimental Station, has made anatomical studies of this apparent reversal of chlorophyll content in *Hyoscyamus* virus III as it attacks the tobacco plant (*Ann. App. Biol.*, 25, No. 4, 781; 1938). The yellow colour of cleared veins is due to retardation of chlorophyll formation; no anatomical or cytological abnormalities occur at this stage. When bands of green tissue appear along the veins, however, the green parts are thicker than normal, whilst the interveinal yellow areas are thinner. Intracellular inclusions are abundant in all tissues except the xylem, but the virus is 6-11 times more concentrated in the yellow cleared tissue than in the green, banded tissue. The findings agree, in general, with those of other workers using different host-virus combinations.

Tetraploid Pears

A bud sport from the 'Fertility' pear ($2n = 34$) has occurred in Messrs. Seabrook's Nurseries. This new form, called 'Improved Fertility', exhibits increased size in all its parts. The average weight of each fruit is 197.5 gm. compared with 125 gm. in the original form. M. B. Crane and P. T. Thomas (*J. Genetics*, 37, 287-300; 1939) have analysed the new form and found it to be a tetraploid $2n = 68$. This 'Improved Fertility' is more self-fertile than the original diploid form and may give rise to further desirable tetraploid varieties of pears. The diploid form, although known in commerce for sixty years, is comparatively unstable and sometimes shows aberrant cell divisions.

Strength of the Earth's Outer Shells

R. A. DALY has recently reconsidered this question on a world-wide scale in the light of the evidence of gravity anomalies, the figure of the earth and physical geology (*Amer. J. Sci.*, 35, 401; 1938). From recent data obtained by Hirvonen in the glaciated tract of north-west Europe "it appears that the asthenosphere can have at most only a minute fraction of the strength attributed to it by either Barrell or Jeffreys". The positive or negative loads would in this case have to be borne either by the earth's crust or by a 'centrospheric' shell, either or both of which would

need to have considerable strength, especially to shearing stress and bending moments. Further, the gravity anomalies obtained in peninsular India are hard to reconcile with the present earth model unless a triaxial figure of the earth is used, corresponding with one of those deduced by Hirvonen, Helmert, Berroth or Heiskanen. The proposed new model also contains proportions of sial and crystalline sima to account for the facts of physical geology, the whole being supported on a vitreous substratum which has a configuration similar to the earth's geographical features but more accentuated, this substratum producing the isostatic compensation. The elevations in the vitreous substratum directly under the continents and mountain chains are called 'anti-roots'.

Configuration of Chitosamine

CHITOSAMINE, the amino-hexose from chitin, has been alternatively described as glucosamine or mannosamine and numerous attempts to solve this problem of configuration have been made. W. N. Haworth, W. H. G. Lake and S. Peat (*J. Chem. Soc.*, 271; 1939) have now shown that a dimethyl 2:3-anhydromethyl mannoside gives rise, with alkali or sodium methoxide, to both a glucose derivative and an altrose derivative. The opening of the anhydro-ring in the dimethyl 2:3-anhydromethyl mannoside by ammonia gave rise to a derivative of 3-amino-altrose on the one hand and of 2-amino-glucose on the other. The latter substance was shown to be identical with chitosamine, which may now be considered configurationally to be glucose amine and therefore related to the parent sugar glucose.

Deuterium Content of Mixtures

An improved method of determining the deuterium content in mixtures of H_2O and D_2O is described by K. Linderström-Lang, O. Jacobsen and G. Johansen (*O.R. Lab. Carlsberg, Série chimique*, 23; No. 5; 1938). The apparatus consists of a vertical glass tube containing a heterogeneous mixture of kerosene and bromobenzene the density of which varies linearly with the height. One drop of the aqueous solution is added and falls to a position of equilibrium in which its density is equal to that of the medium there. The position of the drop is read off by a horizontal microscope and compared with the positions of standard drops of known densities. Only a very small amount of the water (1 cub. mm.) is required. The experimental procedure is described, particularly the purification of the water samples before measurement.

Sliding Friction and the Contact between Surfaces

F. P. Bowden and L. Leben (*Proc. Roy. Soc.*, A, 169, 371; 1939) have investigated in detail the sliding of one surface over another. The lower of two surfaces was moved slowly and very regularly, another surface was pressed against it and dragged against a spring control which measured the frictional force. It was found that the sliding always took place in a series of jerks. The upper surface was first carried forward with the same velocity as the lower, then there was a rapid slip, followed by a further period of sticking, and so on. This effect was observed with ordinarily clean surfaces and with surfaces lubricated with mineral oils. If certain long-chain fatty acids were used as lubricants, the sticking and slipping disappeared and motion became con-

tinuous. The friction between surfaces of like metals showed a large and violently fluctuating frictional force instead of the regular slipping and sticking. The experiments suggest that friction is due to a welding together of the materials at local points of contact. When the welded junctions are broken, the metal is distorted to a depth large on an atomic scale. Bowden and D. Faber, in the following paper, have estimated the area of contact between metal surfaces from the electrical resistance of the interface, and by visual examination of the impressions formed. They conclude that for flat stationary surfaces the area of intimate contact may be only 1/10,000 of the apparent area. The area of true contact is not greatly affected by the size, shape or roughness of the surface, but it depends mainly on the pressure. The local pressures are probably such that steel and similar materials undergo plastic deformation. Measurements made with moving surfaces show that the area of contact is not constant, but changes rapidly with the sticking and slipping of the sliding surfaces. The variations in contact area were compatible with the view that sliding consists in the alternate formation and rupture of metallic junctions.

A Falling-Weight Time Switch

BEFORE a meeting of the Physical Society of London, held on March 10, Eric J. Irons read a paper prepared by him in co-operation with G. A. Bennet in which they described a falling-weight time switch. In this apparatus, the simultaneous release of two steel balls, the one from a fixed height and the other from a variable but known height H effects the operation of two switches at a time interval which is shown to be a linear function of $\sqrt{H}$. An electrical circuit is arranged so that the fall of the first ball disconnects the battery and allows the condenser in circuit with it to discharge through a resistance R , until the impact of the second ball opens a switch and breaks the circuit. The potential difference between the plates of the condenser is estimated at this instant by observing the kick of the galvanometer which is simultaneously put in circuit with it. The logarithm of this value plotted against $\sqrt{H}$ gives a straight line, which substantiates the required relation and whose gradient yields the value of g with an accuracy of one half of one per cent. In the second part of the paper, the authors explained the application of the two-sphere arrangement to the study of the relation between current and time in an inductive circuit.

Colour Photography of the Lunar Eclipse of Nov. 7, 1938

B. BURRELL has recently published a paper with this title (*J. Brit. Astro. Assoc.*, 49, 4; 1939) in which he describes the results of his records of this eclipse on colour-recording film. He used Agfacolor as a suitable material and obtained altogether forty-eight exposures, the telescope being a 3-inch refractor, mounted on an equatorial head. As there was no driving-clock, guiding was done by the finder; but this proved rather difficult, especially when the centre of the disk was in the umbra, as the eye was then dazzled by the strong penumbral light. A table shows the results obtained for various phases of the eclipse. The centre of the umbra at the beginning of totality was a very deep brown, shading to orange at the N. limb. Later the whole umbra brightened up considerably until about 0h, after which it remained constant.

The South-West Essex Technical College and School of Art

WHEN the historian of the future makes a survey of the development of education in Great Britain, he will undoubtedly consider the rapid advance in all forms of technical education as the characteristic feature of the present period. We who live in the period may perhaps be too near the gradual evolution to appreciate fully its magnitude and far-reaching effects. Yet, when one county, and that not a large nor highly industrial one, can, within a few years, erect two large technical colleges, only a few miles apart, each costing more than

The building is, in plan, shaped like the letter E and faces south. It covers an area of two and a quarter acres and is designed in the Georgian style, faced with multi-coloured bricks that contrast with the rusticated plinth, cornice and window dressings. It contains four floors, and the main entrance, placed at the top of a bold flight of steps, is rendered beautifully conspicuous by its portico of artificial stone supported by six Corinthian columns and surrounded by a pediment. The west wing, forming the upper prong of the E, is occupied by the departments of

£200,000 and accommodating 6,000 evening and 1,100 day students, there can be no doubt that this mechanized age has forced the pace of technical education very considerably.

The increased demand for more adequate facilities for practical education, together with the rapid development of many suburban districts due to the migration of the population, led the Essex Education Authority in 1933 to devise a regional scheme. The county was divided into four regions having centres at Colchester, Chelmsford, Dagenham and Walthamstow. Technical schools were already in existence in several districts, but to meet modern requirements, it was decided to enlarge and re-equip those at Colchester and Chelmsford and to erect entirely new buildings at Dagenham and Walthamstow. The South-East Essex Technical College, situated on spacious grounds on the south side of Longbridge Road about two miles from Barking station, was officially opened in 1936 and a brief account of this huge college appeared in *NATURE* of March 27, 1937. The fourth region is served by the South-West Essex Technical College and School of Art, situated on a large site in Forest Road, Walthamstow. This magnificent edifice was opened on February 28, 1939, by the Right Hon. The Earl de la Warr, president of the Board of Education. It is designed to serve the Boroughs of Walthamstow, Leyton, Chingford and Wanstead and Woodford together with the smaller districts of Waltham, Epping and Ongar.

science, commerce, domestic science and building, with a well-equipped gymnasium at the north end. In the east wing are to be found the School of Art and, at the northern extremity, a second gymnasium. Between the two gymnasia, provision in the form of a separate one-story building has been made for the engineering workshops. The central prong of the E actually forms the main axis of the College and contains the large and spacious assembly hall on the ground floor with the swimming bath below in the basement, and above, the library on the first floor with a refectory and kitchens on the second floor. The great hall, 100 ft. long, 55 ft. wide and 22 ft. high, will seat more than one thousand people and is provided, at the north end, with a stage 20 ft. deep completely equipped for modern dramatic and operatic productions. The swimming pool, fitted with springboards, diving stage, changing and shower rooms, is 100 ft. by 42 ft. and is illuminated by specially devised ceiling lights.

The frontage block—the vertical stroke of the E—contains staff rooms in the basement; chemical and physical laboratories, with storage and lecture rooms on the lower ground floor; administrative offices, board-room, etc., on the ground floor, and above, on the top floor, special rooms for bookkeeping, commodities and retail trades. One special room should be noted in this block. On the ground floor nearly opposite the board-room is the nursery where mothers may leave their children in the care of a trained nurse

while they are attending classes! The corridor floors are covered with grey mottled rubber to render the movement of students as silent as possible, and supplementary to the main staircases, passenger lifts have been installed.

It was John Ruskin who wrote, many years ago, "The entire object of true education is to make people not merely do the right things but enjoy the right things". Yet, the pioneers of technical education were mainly concerned with providing a training which was severely utilitarian. But, as Dr. H. Lowery, the principal of the College, aptly points out, "A new problem . . . has arisen—it becomes necessary to provide training for *leisure* as well as for *vocation*". Here then is a new function implying heavy responsibilities for the modern college. It is essential to recognize and to cater for the proper use of leisure, and here, in this magnificent new institution, ample opportunities are afforded for developing the true recreational and communal spirit. To quote

Dr. Lowery again, "it is our desire that the College shall become one great educational and recreational community centre where men and women may meet in their leisure time for the purpose of engaging in matters of common interest, thereby securing the fullest opportunity for self-expression".

The material building of this huge college has been very efficiently carried out by the general contractors, Messrs. F. R. Hipperson and Son, Ltd., of London, to the plans of Mr. J. Stuart, the architect, but an even greater work will now be undertaken by the principal and his large staff in laying the foundations of another edifice which will undoubtedly reveal itself in the trained mind, skilled craftsmanship, cultured recreation and, what is most important of all, trustworthiness and reliability of character. As R. W. Dale once wrote: "The immediately possible is hardly worth living for. It is the ideal that kindles enthusiasm and gives inspiration and vigour to all human effort".

F. G. W. B.

Peneplains and Related Land Forms

IT is now nearly fifty years since W. M. Davis introduced the term 'peneplain' for the surface of low relief which might be expected to mark the end-stages of a long period of sub-aerial erosion under stable conditions. The term was received with a certain suspicion and lack of cordiality among British workers and it has been used comparatively little in their writings. Geographers and geomorphologists will therefore note with interest that the Geological Society recently discussed some of the questions at issue.

In introducing the subject, Dr. F. Dixey's main contention was that the term 'peneplain' is properly applicable to local areas which, though extensive, are far from being of continental dimensions. The common presentation of a cycle of erosion as running its course in a region of homogeneous rocks and resulting ultimately in the base-levelling of a whole land mass leads, in his view, to an unwarrantable attempt to limit the application of the term peneplain. He directed attention to the "two-peneplain topography" described by A. D. Coombe in Uganda, and common indeed throughout Africa, and he showed that such conditions must inevitably arise where weak and resistant rock-masses are juxtaposed. The lower surface opened out in weaker rocks, such, for example, as unfaulted strips of Karroo sediments, may have the characteristics of a true peneplain, even though locally interrupted by residual masses and abutting elsewhere against steep slopes. Thus there arose veritable flights of peneplains as between the northern end of the Nyasa rift and the Luangwa valley. Here the following erosion surfaces are distinguishable: a late Jurassic surface at about 7,000 ft., a late Cretaceous or Early Tertiary surface at 5,000 ft., a Miocene surface at 4,000 ft., and a late Tertiary surface developed at about 3,000 ft. on friable Cretaceous rocks in local troughs. Further, a sub-Cretaceous surface has been exhumed locally by erosion and stands at about 2,000 ft. This surface and the late Tertiary surface rank as local peneplains in Dr. Dixey's sense, though others have denied them

such rank because they are enclosed by highland areas.

Most other contributors to the discussion expressed agreement with Dr. Dixey, and Mr. J. M. Edmonds described somewhat comparable conditions in the Anglo-Egyptian Sudan. Dr. K. C. Dunham, however, noted that the Rio Grande and the Gila River are flanked by erosion surfaces, up to 80 miles long and 30 miles wide, produced by lateral corrosion. These would apparently rank as local peneplains in Dixey's scheme, but he thought this constituted an extension of the term peneplain and one unlikely to prove acceptable to American workers.

The discussion ranged widely over other cognate matters and several points of view were represented. Prof. O. T. Jones deplored the lack of any agreed definition of the features of a peneplain. He maintained that, in one sense, the whole of England and most of Wales is a peneplain rising gently from sea-level to more than 2,000 ft., and truncating all formations from the Pre-Cambrian to the Pliocene. Despite the considerable relief of parts of this surface, such relief can scarcely amount to 10 per cent of the thickness of strata removed by erosion. He also emphasized the probable importance of wind erosion in producing extensive surfaces of low relief.

Other speakers were, by implication at least, unwilling to accept so wide and general a connotation for the term 'peneplain'. Dr. Hollingworth pointed out that Davis's conception of a single peneplain in the Appalachian region is now challenged by several alternative and mutually inconsistent interpretations, most of which agree, at least, in representing the surface as complex and composite. Similarly, Mr. J. F. N. Green expressed the belief that many surfaces in the south of England which might be regarded as peneplains on general inspection have proved susceptible of dissection into distinct terrace-like features, separated by bluffs. Mr. A. A. Miller and Dr. S. W. Wooldridge raised a further issue in pointing out that many of the 'high-level platforms' of Britain, as well as most of the 'fossil' surfaces.

that is, exhumed planes of unconformity, have been finished, if not formed, by marine agency. In many such cases it is clear that the drainage pattern has not been inherited from a previous cycle, as must inevitably be the case with a true peneplain. Thus, closely spaced wind-gaps in the Old Red Sandstone ridges of southern Ireland indicate a consequent drainage initiated upon the surface which bevelled the structures. Similarly, the transection of antilinal lines by rivers in southern England indicates that over wide areas the drainage originated upon the emergent floor of a Pliocene sea. Nevertheless, the whole of the region was not submerged; in parts of the Chalk areas of Wessex and the central Wealden area the reconstructed hill-top plane reveals the characteristics of a true peneplain and the drainage was adjusted accordingly. It seems, moreover, that the Thames in earlier stages of its history cut wide

benches by lateral corrosion which may fairly be grouped with Crickmay's 'panplains' and the American examples adduced by Dr. Dunham.

The discussion gave a clear indication, if such be needed, that the findings of geomorphology in the field of erosion surfaces now challenge the close attention of the stratigraphical geologist and the geophysicist. Erosion surfaces, some trimmed by marine erosion and others demonstrably of sub-aerial origin, have been proved to have a wide extension and to maintain essentially unwarped attitudes over great distances. As such, they constitute an important record of the later geological history of the continents, supplementing the sometimes scanty evidence of deposition. Further, their existence cannot be ignored by those who seek to understand the nature and extent of isostatic adjustment in the lithosphere.

S. W. WOOLDRIDGE.

Physics in the Textile Industries

RESEARCH physicists working in industry continue to increase in number, and the Institute of Physics, by holding conferences on industrial physics, does much to bring them together to discuss their mutual problems. But the conferences are open to all interested, and the physicist has opportunities of making contacts with those of other professions whose problems are essentially physical.

The third conference, held in Leeds during March 23-25, was devoted to "Physics in the Textile Industries". The textile industries have been built up by many years of experimenting coupled with notable inventions, and it has behind it a wealth of knowledge which must be learnt by the physicist if his work is to be of utmost advantage to the industry. Meetings such as that held in Leeds are thus of great value in enabling the physicist to discuss problems not only with other physicists, but also with those conversant with the industry. Simultaneously, the industrial technical man has an opportunity of learning possible applications of physics and physical devices to his industry. This is particularly important for the older textile industries, where few factories have physicists on their permanent staff, and advances which physics has to offer must be introduced and cared for by the technical men.

The conference was held in the Physics Department of the University of Leeds. It was formally opened by the Vice-Chancellor, Mr. B. Mouat Jones, and was presided over by Prof. R. Whiddington. Following established practice of the Institute, the lectures and discussions were informal, and will not all be published.

The formal opening was followed by an address by Prof. Whiddington on "The Physics of Humidity". He discussed with demonstrations the properties of the small but important amounts of water in the atmosphere, and indicated why relative humidity is for the textile industries a much more convenient measure of the quantity of water vapour in the air than the fundamental measure, vapour pressure. He then described properties of substances dependent on water content, and illustrated experimentally the large heat effects associated with change in water content of textile fibres. He concluded with an experi-

ment showing the swelling of a wool fibre with increase of water content, using as a micrometer the capacity of a condenser in a heterodyne circuit. Thursday morning's programme was completed by a lecture from Dr. Ezer Griffiths, of the National Physical Laboratory, on "Industrial Humidity Control and Measurement". He illustrated with many slides the requirements of humidifying plant and humidity controls, and described the various ways of measuring relative humidity, indicating the method most convenient to each industrial process where this is important.

The afternoon of March 23 was devoted to a visit to the Department of Textile Industries in the University, followed by Dr. C. C. Paterson's presidential address to the Institute of Physics. He chose as his subject "Colour and Colour Rendering". This was a lecture of exceptionally beautiful and instructive demonstrations. Dr. Paterson pointed out the high efficiency attainable from discharge tube lamps, and contrasted their spectra and colour-rendering properties with daylight and other sources of illumination. The colour triangle and C.I.E. units were simply and elegantly explained, and there followed striking demonstrations of the difference between matched white lights for colour rendering. He pointed out that the appraisal of colour matching value is a pressing but unsolved problem. The lecture concluded with illustrations of the improvement in colour quality and efficiency attainable in discharge tube lamps by use of fluorescent materials.

The lectures on March 24 were by Dr. M. O. Marsh, of the Cambridge Instrument Co., Ltd., who chose "The Contribution of Physics to the Development of Industrial Process Control", and by Mr. D. Harrison, who spoke on "Automatic Regulators for the Textile Industries". These lectures brought to the notice of all the many instruments now available for industry, and features of their design gave an impressive illustration of the potentialities of physical knowledge when applied to industry.

The final lecture of the meeting was on "Heat Effects in Fibres and other Systems". It was given by Dr. C. G. Darwin, director of the National Physical Laboratory. It was a delightful lecture on a difficult

and controversial subject. Kinetic effects have of recent years been used to explain the long-range elasticity of many natural substances, particularly rubber, and suggestions have from time to time been made that the same principles may lie behind the exceptional elasticity of muscle, wool fibres, and various synthetic materials. Dr. Darwin outlined the thermodynamic and statistical arguments of equipartition of energy and entropy, and used them in a critical survey of explanations of long-range elasticity. He showed, too, how these same kinetic principles led to the use of adiabatic demagnetization for attainment of very deep temperatures.

On Friday evening and Saturday morning, members of the Conference saw much of science in the textile industries at the laboratories of the Wool Industries Research Association. Alternative visits on Saturday morning to the Bradford Conditioning House and to Messrs. Prince-Smith and Stells, Ltd., Keighley, enabled members to appreciate the extent of testing of textile materials, and the ingenuity that has been used in design of textile machinery.

An exhibition of apparatus, instruments and books cognate to the subject of the conference was held in

the physics laboratories of the University. Twenty-six firms and research organisations, including the National Physical Laboratory, had stands at the Exhibition. A special section devoted to popular applications of physics calculated to demonstrate its varied application to everyday matters, especially in the manufacture and use of textiles, aroused much interest. Representative instrument makers contributed exhibits which served to show how many and varied are the instruments available to help the textile manufacturer overcome many of the difficulties inherent in producing a uniform product from variable raw materials. The exhibition was of inestimable value in suggesting to textile manufacturers the large variety of problems that physics may tackle.

The Institute of Physics assumed a difficult task in choosing "Physics in the Textile Industries" as the subject for its third conference. Physics is becoming better recognized by textile manufacturers, but its progress in the industry has proved difficult and slow. The success of the conference and the attention it has attracted should advance the application of physics in one of the largest industries of Great Britain, and in turn help it to meet ever-increasing competition from abroad. A. B. D. CASSIE.

Forest Administration in Malaya

THE Forestry Department of the Straits Settlements and the Federated Malay States was organized in 1901 and the Malayan Forest Service, which includes all senior officers serving in Malaya, was created in 1926. Afterwards, the protected States of Johore (1920), Kedah (1923), Kelantan (1933), Brunei (1933) and Trengganu (1936) set up forestry departments of their own, to the charge of which officers of the Malayan Forest Service were appointed. A Research Branch was commenced in 1918, and has greatly developed and undertaken important work, its sections now consisting of botany, wood anatomy, silviculture, chemistry, entomology, forest economy and timber testing. In connexion with the Research Branch, a vernacular school is maintained for the training of the subordinate staff. The Research Branch and School are now much on the same lines as the classic example at Dehra Dun, India.

Decentralization took place in 1935, and the Malayan forest organisation is now defined as a group of ten forest departments held together by a common and interchangeable staff of trained officers "with a central coordinating body (including the director of forestry), with executive control in some territories and advisory duties in others, that always exerts some influence towards co-operation and a broadly common forest policy". So long as the central co-ordinating body is listened to, progress in the future should be as good and better than the past. But decentralization is a dangerous thing in forestry—as can be seen in many parts of the forestry world in the British Empire. The required area of forests to be reserved in the interest of the individual country as a whole, stock mapping in forests under exploitation or shortly to be exploited, and, that safeguard of the forests, the working plan—these three essentials to a correct administration of a country are in one or more cases, and often in all three, lagging seriously behind what is needed in many parts of the Empire.

When this is the position—and in how much of our Empire outside India is this the case—decentralization and the withdrawal or even lightening of the control of a central authority responsible for a large region of country is seriously to be deprecated.

That this latter contention merits attention is shown by the statement contained in the "Annual Report on Forest Administration in Malaya for 1937" (F.M.S. Govt. Press, Kuala Lumpur, 1938). The Director writes, "Some uneasiness has however been caused by sudden and unexpected demands for the release of extensive areas that have always been regarded as permanent reserves. Thus, in Tabang the Teluk reserve of 83,000 acres had to be relinquished for inclusion in the King George V National Park, in this way preventing the exploitation of some particularly good *merbau* forest, conveniently situated near the railway. In Perak practically the whole of Pasir Panjang Ulu reserve of 19,000 acres was earmarked for a *padi* irrigation scheme, innumerable applications were received for permits to prospect for minerals and a strong bid was made by Sakai to settle in an old-established reserve that is by no means too large to meet the needs of the surrounding population and in which regeneration operations have been carried out for years at considerable expense to Government. This department is far from being unsympathetic to the claims of these various communities and realizes that adjustments will be necessary, but the long-range policy that is inseparable from conservative forestry makes it imperative that conflicting interests should be planned far enough in advance to enable systematic forest operations to be undertaken with some prospect of fruition".

Sympathy may be expressed with a department placed in such a situation, but the forestry authorities do not appear to understand that it is one of the objects of and duties of the working plan to safeguard forests from calamities of this type and others.

On the subject of working plans, the Director writes, after alluding to plans for the mangrove forests of Perak and Selangor, "Whereas the plans for the mangrove follow the usual pattern, those for inland forests are much less detailed and will continue so until greater stability is reached in the consuming industries and the threat of revocation is removed. Reference has been made (above) to the existing uncertainty with regard to the permanence of tenure, without which no serious planning is possible".

Why? This was not the policy followed in India; nor is it in Europe. In the centre of France a fine beech forest exists. There is also an industry working out kaolin within the forest. A working plan has been in force for the area for more than eighty years; and yet the manager of the kaolin industry can come to the forest officer any day and say he wants to commence to excavate at such and such spot, thereby involving one or more compartments, which necessitates some adjustments in the working plan and possibly of the yield for some years to come. Once a working plan has been sanctioned for an area of forest by the central authority the latter is not so ready to go back on a considered policy. Areas now threatened in Malaya might never have come into this unenviable position had they been placed under a working plan.

This report is of considerable interest and contains abridged reports of the activities of the Forest Departments of Johore, Kedah, Kelantan, Trengganu and, Brunei.

University Events

CAMBRIDGE.—At a special congregation to be held on June 6, it is proposed to confer the honorary degree of Sc.D. on Prof. W. N. Haworth, Mason professor of chemistry in the University of Birmingham, and on Sir Henry Dale of Trinity College, director of the National Institute for Medical Research, London.

At King's College, Dr. A. E. Alexander has been elected to a fellowship. Dr. Alexander, who was educated at Brookenhurst County School and the University of Reading, obtained a first class in Part II (Chemistry) of the Natural Sciences Tripos in 1935 and was awarded the Gordon Wigan Prize in 1937. He was elected to a Ramsay Memorial fellowship in 1937 and now holds a Rockefeller travelling fellowship.

LONDON.—Dr. G. A. D. Haslewood has been appointed to the University readership in biochemistry tenable at Guy's Hospital Medical School. Since 1935 he has been assistant in pathological chemistry at the British Postgraduate Medical School.

Mr. P. A. Sheppard has been appointed to the University readership in meteorology tenable at the Imperial College of Science and Technology. Since 1934 he has been technical officer in the Department of Meteorology at the Chemical Defence Experimental Station, Porton.

It has been resolved to institute a certificate of proficiency in natural history, and regulations have now been adopted for it.

SHEFFIELD.—Dr. J. Monteath Robertson has been appointed lecturer in physical chemistry, in succession to Dr. S. Glasstone, who has resigned.

Science News a Century Ago

Photography in Germany

Writing from Paris on April 2, 1839, a foreign correspondent of the *Athenaeum* said: "The announcement of Daguerre's discovery has turned the brains of half the world: you sober English have certainly not escaped the infection; and the speculating Germans, as you have noticed, are hard at it. I learn, by letters just received from Munich, that Profs. Steinheil and Robel are astonishing the natives with their Photogenic pictures. It is said that they have discovered the process of the Daguerre, but it seems to me more than probable that their process rather resembles that of Mr. Talbot; and that by their invention pictures can be obtained not only with the aid of the camera obscura but by the direct agency of light so that they take, in an instant, copies of pictures traced upon blackened glass. . . . Daguerre's pictures are, it is known, traced upon copper (?) but Messrs. Steinheil and Robel imprint theirs upon paper."

Application of Döbereiner's Discovery

In a letter to the *Mechanics' Magazine*, sent from Sandwich on April 5, 1839, W. H. Weekes referred to "a suggestion of my own made many years since, with a view to effect the simultaneous lighting of street lamps throughout a town or district". Weekes had been accustomed, by means of a private press, to keep memoranda in printed form, and one of these dated January 24, 1826, he sent to the editor of the journal. In this memorandum he had written: "One of the most interesting facts as connected with the recent advancement of modern chemical science, perhaps, is the important discovery of that intelligent continental philosopher Döbereiner, who has ascertained the peculiar property of *spongy platinum* to become ignited by exposure to the action of a stream of hydrogen gas, and the consequent inflammation of the gas itself, from contact with the ignited metal; thus furnishing a most ingenious, elegant and useful mode of obtaining instantaneous light. . . . Now, will similar results obtain from the action of *spongy platinum* on the gaseous compound carburetted hydrogen or coal gas? Of this I think there can be little doubt, and if proved the spongy platinum may unquestionably be rendered applicable to the purpose of lighting street lamps spontaneously."

Johann Wolfgang Döbereiner, the German chemist who discovered the property of spongy platinum referred to, was born December 15, 1780, and died March 24, 1849.

Seasons and Infantile Mortality

THE issue of the *British and Foreign Medical Review* of April 1839 contains the following information: "The season of the year evidently exercises great influence on the rate of the mortality of children. According to Trevisan, of 100 children born in Italy in the winter 66 die in the first month, and only 19 survive the first year; on the other hand, of 100 children born in summer so many as 83 survive the first year, of 100 born in the spring 48, of 100 born in the autumn 58. In Belgium the rate of mortality in the first month of children born in January, compared with that of children born in July is 33.21 to 17.19."

Societies and Academies

London

Royal Society (*Proc.*, B, 127, 1-139; 1939).

T. SVEDBERG and others: A discussion on the protein molecule.

F. C. COURTICE, C. G. DOUGLAS and J. G. PRIESTLEY: Carbohydrate metabolism and muscular exercise.

W. S. STILES: Directional sensitivity of the retina, and the spectral sensitivities of the rods and cones.

C. RIMINGTON: A re-investigation of turacin, the copper porphyrin pigment of certain birds belonging to the Musophagidae.

P. K. DE: Role of blue-green algae in nitrogen fixation in rice-fields.

Paris

Academy of Sciences (*C.R.*, 208, 609-684, Feb. 27, 1939).

A. LACROIX: Submarine volcanoes, in connexion with some rhyolitic pumices collected on the atoll Marutea du Sud (Tuamotu Archipelago).

R. ROSCA: Asymptotic transformations of curves in elliptic space.

A. TERRACINI: Existence of surfaces having given principal lines.

J. TOUCHARD: Differential equation of third order sines.

G. KOWALCZEWSKI: An unknown property of the plane projective group.

V. ROMANOVSKY: Eddies in thick sediments: application to polygonal strata of the Arctic. Layers of sugar, salt or sand, covered with a layer of water and heated nearly to boiling point, give convection 'cells' identical in form with the polygonally marked areas of Greenland and Spitsbergen.

L. ESCANDE: Experiments on the outflow of a weir barrage.

G. DEMBANT and P. WEHLE: Definition of turbulence.

J. VILLY and R. JAMIN: Law of variation of the force opposed by the air to the translation of a movable body.

H. MINNIB: Evolution of galactic clusters.

H. GROUILLER: Photographic and colorimetric photometry of the eclipsing double star β Lyrae.

J. VIGNAL: Probable chief cause of imperfection of modern levellings.

I. OPATOWSKI: Integration of the equations of motion of an electrified particle of variable mass subjected to the action of electric or magnetic fields of any kind.

J. MARIANI: Existence of an elementary quantum of length.

L. NIEL and B. PERSOZ: New method of measuring true specific heats of metals at high temperature. The metal in the form of a wire, 0.5 mm. thick and 10 cm. long, in a furnace at a given temperature is heated by an intense current for about 0.1 sec. and the rise of temperature measured by using the wire as a branch of a double Thomson bridge.

S. NIKITINE: Theory of transversal photodiachroism.

P. SAVITCH: A gaseous radio-element formed by the bombardment of uranium by neutrons. The new

element is a gas emitting β -radiation and its period is about 20 min.

F. JOLIOT: Observation by the Wilson method of the cloud trajectories of the products of the explosion of the uranium nucleus. On one photograph out of 902 taken, a track indicating an atom of ionizing power four times that of an alpha-ray was found.

T. KAHAN: Transmutations of light nuclei and their theoretical interpretation. A series of reactions in cascade is suggested.

J. THIBAUD and A. MOUSSA: Disintegration of uranium by neutrons and the partition of this element. Chemical separation shows that uranium breaks up into lanthanum and bromine, which are transformed by a series of β -disintegrations into strontium and a rare earth respectively. Particles of energy of the order of 50 Mev. are released.

A. DOGNON and C. PIFFAUT: Absence of denaturation by heat of superficial solutions of serum albumin.

A. N. STOUTITSKY: (1) Thyreotropic response in the chick embryo. (2) Parathyreotropic response in the chick embryo.

M. P. ALEXUPR: Regeneration processes in the developing bone.

Z. IGNATIEVA: Differentiation of neuroblasts in cultures.

Tokyo

Imperial Academy (Proc., 15, No. 1, 1-21; 1939).

SHŌKICHI IYANAGA: Proof of the invariance of fundamental groups by the subdivision of complexes.

KAKUJI GOTO and HIDEMO SHISHIDO: Constitution of tuduranine. This is an accessory alkaloid of sinomenine in the root of *Sinomenium acutum* Rehd. et Wils., and is shown to be the 1-form of 3-oxy-5, 6-dimethoxy-N-por-sporphine.

KOZO HIROTA and JURO HORIUTI: An electrical phenomenon of a palladium filament occluding hydrogen.

YOSHIAKAZU TOYOHARA: Inclination of the strand along a sandy seashore.

SOICHI FUKUDA: Acceleration of development of the silkworm ovary by transplantation into the young pupa. Rapid development is obtained by transplantation into a pupa of either sex, regardless of the presence or absence of gonads.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

PROFESSOR OF ECONOMICS in University College, Swansea—The Registrar (April 3).

JUNIOR LECTURER IN SCIENCE (advanced electrical theory) in the Royal Military Academy, Woolwich—The Under-Secretary of State (O.S.), The War Office, London, S.W.1 (April 8).

LECTURER IN HORTICULTURE AND NATURE STUDY in the Strandmill Training College, Belfast—The Principal (April 15).

ASSISTANT LECTURER IN DOMESTIC SUBJECTS in the University of Reading—The Registrar (April 17).

LECTURER IN PHYSICS in the School of Science, Khartoum—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, London, S.W.1 (May 15).

Scientific Research and the National Register

OF the importance of the part that will be played by men of science in the activities of any country that is, unhappily, engaged in modern warfare, there is no question. All are agreed on that point, and it is deeply to be deplored that the same agreement is not to be found concerning the contribution which they can make, and are ready to make, towards the solution of many of our peace-time problems, nor is the same desire shown to develop organizations which may serve to harness their abilities to that end. It is the tragedy of the times in which we live, that the forces of peace are unorganized, though collectively they are impressive enough in magnitude, and that the threat of war should be needed to orient and to organize man's activities to serve a common national need.

The best for which we can hope, in the present state of muddled thinking on the part of those to whom the nations of the world have confided their destinies, is that, should the shadow of war be lifted from the world, the organizations which the threat of war has called into being may be redirected and extended to serve more worthy ends. This has been done successfully in the past. The Ordnance Survey of Great Britain, which has developed almost beyond recognition since its inception at the end of the eighteenth century, and the pacific activities of which far transcend its wartime usefulness, took its origin from a war-measure ; and it needed the stress of the war of 1914-18 to call into being the Department of Scientific and Industrial Research. The plain truth is that man is an unimaginative creature, and Bastiat's argument concerning what is seen and what is not seen is pertinent to many more realms of thought than the economic one. Everyone's imagination is shocked by the thought of a great modern city

pounded to a heap of smoking ashes ; it is not so easy, in a bustling cheerful town, with cinemas filled to overflowing, and shops exhibiting merchandise gathered from the four corners of the earth, to realize that the country is faced with grave problems of malnutrition, problems the solution of which demands as close co-operation, as much teamwork, and as high and devoted enthusiasm as ever were brought to bear on a war-time problem. To-morrow is time enough for the problems which are not seen ; the threat of war brings with it problems to be attacked to-day.

Among the needs of Great Britain at the present time is a register of names of those possessing professional, scientific, technical and higher administrative qualifications. Concerning the war-time value of such a register, there is no question ; and it should be equally evident that it will have a high value for a nation which is awakening to the need for a successful attack on the problems of peace. It is the first step towards that co-ordination of our expert services which is so urgently needed ; on the scientific side, it is the first instalment of that catalogue which will help us make a mental picture of the research activities of the country—to show us, in fact, what lack of co-ordination exists, what avoidable overlappings are evident, what gaps in our research problems need filling, and where border-line problems may most profitably be attacked.

The National Service Department of the Ministry of Labour is compiling such a register, and the register, in the event of war, will provide for the Government a list of persons willing to serve in their professional capacities in some appropriate way. The emphasis here is on the word 'appropriate'. The National Service Department is fully

alive to the consequences of the errors of assignment made in the war of 1914-18, and is anxious to avoid a repetition of those errors, and to ensure that each man who offers his services is assigned to that task for which his knowledge, training and capacities best fit him. To that end the Royal Society has been asked to co-operate by compiling the section of the register dealing with persons "*normally engaged in, or qualified to undertake, scientific research*". These terms of reference should be carefully noted, for the register will defeat its own ends if it consists of an *omnium gatherum* of all persons who may be said to have had a scientific training, or who, without any special qualifications for research, are normally engaged in more or less routine work of a scientific character.

The officers of learned societies, and the heads of scientific departments in university and similar research institutions, have been asked by the Royal Society to furnish a list of those persons to whom an inquiry should be sent, and it is important here to note the relation between the Scientific Research Register and the Universities Register which was undertaken some months ago. Possibilities of overlap, confusion and of endless filling-in of forms are present in the minds of many inquirers, and it should be borne in mind that the Scientific Research Register undertaken for the Ministry of Labour by the Royal Society, as it is the latest, will probably be the last of its kind, and that it differs in three important respects from the Universities Register. In the first place, inclusion in the Scientific Register implies an *obligation*, "to serve [in wartime] in an appropriate way in their professional capacity and to accept such suitable work as is offered to them". It is perhaps desirable to emphasize this obligation, and to point out that the sub-committees set up to advise in the several subjects and to consider in advance the most suitable employment of individuals, consist of scientific men, who will approach their task with full knowledge. No obligation was, of course, implied in the Universities Register.

Again, the names of individuals included in the Scientific Research Register will not be included in the Universities Register. It is necessary to have a single register for all persons normally engaged in, or qualified to undertake, scientific research. It is obvious that a large proportion of such persons will not be in the universities, and it is therefore desirable to separate the two registers.

In the third place, the cards for the Universities

Register do not supply certain items of information which are regarded as important for the Scientific Research Register. In particular, no provision was made for that detailed classification of the individual's special qualifications, which is particularly important for the rapid and efficient use of the register.

The Ministry of Labour has set up a special Committee for Scientific Research of the Central Register Advisory Council, which will have the duty of dealing with the information given on the cards of this latest register. The names of the members of this Committee, which are given on another page (p. 592), and of the co-opted members of the various sub-committees, afford sufficient guarantee that the problems of assignment will be handled efficiently and sympathetically, and that there is little danger, say, of the expert chemist's finding himself allotted to the elucidation of a problem in hydrodynamics, or being haled off to busy himself with minor work of an administrative kind.

The Scientific Research Register, it must be remembered, is part of a larger scheme, for the Ministry of Labour is engaged in compiling a Central Register of nine sections of which the Scientific Research Register is one, the remaining registers being devoted to General Engineering, Mining and Metallurgy, Industrial Chemistry, Architecture and Public Utilities, Universities and Teaching, Administration and Management, Accountancy, and Journalism, Languages, etc. It is inevitable that overlap will occur, and in such cases cross-references will be made.

The institution of such a register marks a great advance in the co-ordination of the national services of Great Britain and in the availability of the nation's experts. It is a signal advantage to have the information contained therein collected by one Department, and set out in a consistent fashion, so as to be readily available. The immediate stimulus for the production of this register is the spectre of war, on a scale and of an efficiency which are terrifying to contemplate. This, however, should not deter scientific workers from doing their part in making the register as comprehensive as possible; for, with due provision for keeping it up to date, it should be a lasting foundation on which to build up a scientific service covering all the activities of the nation in peace as well as in war, in preparation for the time when the gifts of science to mankind shall become the keystone of progressive civilization.

Scientific Biography and Correspondence

By Dr. J. F. Scott. Pp. xi + 240. (London : Taylor and Francis, Ltd., 1938.) 12s. 6d.

(4) Briefe Franz Xaver Freiherrn von Zach und seines Nachfolgers Bernhards von Lindenau von 1791-1816 an P. Martin Alois David Herausgegeben von Otto Seydl. (Publikace Pražské Státní Hvězdárny, C. 11.) Pp. 206. (Praha : Státní Hvězdárny Republiky Československé, 1938.) n.p.

THERE may appear to be little to connect these four works beyond the evidence they bear in common to a wider interest in the history of science. This is very welcome. Two of them bear witness further to the active encouragement now given by the University of London to the cultivation of the historical aspect of science. The object is admirable. But it cannot fail to be noticed that success in this line of research is exceedingly difficult of attainment. To the ordinary qualifications of a historian must be added a mature judgment of scientific values. Separately, these are not common qualities ; in conjunction they must be rare indeed.

(1) This book on Copernicus is rather a curious one. It is clearly intended for a wide circle of readers. Perhaps on that account it conveys the estimate of Copernicus which has come to be traditional, as its question-begging sub-title implies. But the true nature of his great work is very fairly explained. It is shown that the mind of Copernicus was Aristotelian to the core and that he followed Ptolemy in the main with great fidelity. So far from being the founder of modern astronomy, it would be far truer to regard his work as the final chapter of the ancient science. It might have been written at any time in the preceding twelve centuries. Indeed, Dreyer has raised the question why the critical step was not taken by Ptolemy himself, and has suggested his own answer. Perhaps the clue is sufficiently revealed in the present

book (p. 155), where the Copernican is claimed as a heliocentric theory, whereas it is stated a few lines before that the longitude of Mars might be 3° in error precisely because the computation is based on a theory which is not heliocentric.

The sketch of the life of Copernicus is drawn from German authorities. It is interesting for the striking justification in a case of episcopal nepotism by which Copernicus profited. His opportunities for education were extended far beyond the ordinary limit, and when he returned to his canonry, ecclesiastical duties seem to have formed the least part of his life. His freedom from theological bias ceases to be surprising.

The account of all earlier planetary theories given in an introductory chapter is necessarily brief. But this was not really needed. What is essential for an understanding of Copernicus and of Kepler is a full explanation of the work of Hipparchus and Ptolemy and, above all, of the terminology associated with the Ptolemaic system. The reader would have gained greatly if his attention had been concentrated on this one vital theory to the exclusion of all competing detail.

The true founders of modern astronomy were Tycho Brahe, Kepler and Galileo. Tycho rejected the Copernican theory, and Kepler superseded it within little more than half a century. Therefore the problem confronting those who wish to maintain that the theory has any great historical importance is to show that, nevertheless, Tycho in his observations and Kepler in his analysis were seriously influenced by it. That is a question which is not approached in this little book.

Though Copernicus had undoubtedly a distinct individuality, his impact on the succeeding age may be quite conveniently attributed to two personalities. There is the Ptolemy-Copernicus concerned with the production of ephemerides, of real though limited interest to the technical astronomer ; there is also the Aristarchus-Copernicus, who is identified in the popular mind with the heliocentric theory. Mr. Armitage has the merit of recognizing the first, but his valuations are based on the second.

(2) The book on Galileo is very readable, but it is disappointing in some respects. The historical background, which includes the counter-reformation, is clearly drawn, and this is a great merit. Details of personal appearance and character and an account of the family relationships add life to the portrait. Of the astronomical observations an adequate description is given. This was the work

of a pioneer in the field, and it is entitled to all the honour which it has received. But, as recriminations over priority show, others were ready to take up and carry on this work, and further advance depended mainly on the improvement of optical resources. The future of telescopic observation was assured, and even in the first step Galileo may have been anticipated by Harriot.

The real importance of Galileo rests on his position as the founder of dynamics. Therefore it might naturally have been expected that the most careful attention would be directed to this part of his work, to his experiments and to his deductions. In this respect the present book is very disappointing. The only reference to the parabolic motion of projectiles is contained in a few lines at the end of the book. The material and Galileo's mode of presentation have not made the task of the biographer easy; but his success must be judged mainly by his treatment of Galileo's achievement in the field of dynamics. Here the account is inadequate.

Two chapters, occupying a quarter of the book, are devoted to the conflict with the Church and the final trial and condemnation of Galileo in 1633. Translations of the principal documents are reproduced at length. The issue may have its importance in ecclesiastical history, but its significance in the history of science is slight. For Galileo, in his declining years, the penalties were heavy, but to these events he owed no small part of his enduring fame. Moreover, as Galileo stood as a champion of Copernicus, the latter owes no little in popular estimation to the same circumstances. All this is very strange because, as can be seen clearly enough now, Galileo, so far from being the bold innovator and leader of the advancing tide, was in sober fact a quarter of a century behind the times.

As early as 1597 Galileo had been in correspondence with Kepler. But when the *Astronomia Nova* appeared in 1609, he must have missed its importance completely. He was not an astronomer in the sense of Tycho; he was rather the first astrophysicist. He was not interested in the theories of Ptolemy-Copernicus, and he never progressed beyond the ideas of Aristarchus-Copernicus, in which he was confirmed by the weak argument from analogy afforded by the satellite system of Jupiter. Otherwise he would not have wasted his time on futile arguments, many of which were thoroughly unsound. But until a more precise meaning was given to the heliocentric theory, no decision could be reached by mere argument. This meaning was given by Kepler when he found that, relative to the sun, both the earth and Mars moved in elliptic orbits with the sun at one focus. After this first approximation, it was not necessary

to wait for the measurement of stellar parallaxes, or even the discovery of aberration, for independent confirmation. The line of further progress was definitely set.

Galileo can scarcely be blamed for failing to appreciate the fundamental importance of Kepler's work. Huygens was equally blind and, making all allowance for half a century's progress, Huygens was a greater man than Galileo. But one contemporary mind did realize immediately the significance of Kepler's work. That was Thomas Harriot.

Galileo, as we are reminded here, was born in the same year as Shakespeare. He died, exactly one year after the death of Horrocks, in that same year which saw the birth of Newton.

(3) A life of John Wallis could scarcely fail to be interesting. Not that he required to be rescued from obscurity, as is here supposed. He has probably not fared worse than most eminent mathematicians, who are always prophets without honour, especially in England. Among mathematicians Wallis holds a high place, and if knowledge of his work has been fragmentary, he has been largely judged perhaps on the *ex pede Herculem* principle, which is not ungenerous. It may be doubted whether the present book adds to his stature or does him full justice.

The most valuable chapter of the book is the fourth, where a full account is given of the representation of π as the limit of a product sequence. The magnitude of the effort needed to reach a point a little in advance of the flowing tide of mathematical progress will be a revelation to all those who have had no occasion to refer to the original work. This was well worth reproducing, for it is a magnificent example of the use of induction and interpolation as a method of research, a method of which Newton also proved himself to be a complete master. As a *tour de force* in this kind, this feat of Wallis is surely unsurpassed, and Newton may well have profited by the example.

Interesting details of the early history of the Royal Society and of the events which led up to its foundation are duly related. But Dr. Scott has two fatal disqualifications as a biographer of Wallis. He is prudishly shocked by the atmosphere of controversy, and he is not technically qualified to form first-hand critical judgments. By accepting everything which has been said to the detriment of Wallis, he has drawn a picture which must be grotesque. For it is utterly incompatible with the position held by Wallis in the Royal Society, which was composed in the main of kindly and gifted men like Wren.

Wallis criticized the Greek mathematicians on the ground that they wished to be admired rather than understood. This fully explains his attitude to Fermat. The resulting controversy was

anything but sterile, and both men may now be regarded as the founders of the theory of numbers. Continued fractions are mentioned only in connexion with Lord Brouncker; but Wallis was the chief founder of that theory also. In the chapter on the "Algebra" the references to Harriot and Descartes are dealt with at disproportionate length without altogether removing an element of mystery. In alluding to Harriot as "a very great man in his time" Wallis was guilty of no exaggeration, and he certainly left papers behind, whether Wallis had seen them or not; the "Praxis" was only published ten years after his death. Down to the time of Harriot, an equation was simply a means to an end, the answer to some problem which required in general a positive and often an integral solution. It was the Cartesian geometry which altered that situation. Wallis, with his sense of generality and of algebraic form, was among the first to see the equation from a mathematical point of view apart from any particular application. In doing so he seems to have confused his own development with the work of Harriot, to which he may well have owed some part of his inspiration. Why, in over-estimating that debt, he should have become increasingly hostile to Descartes is not clear. The only hint is that to Wallis a suspicion of deliberate obscurity was a veritable red rag.

As the work of Wallis on mechanics is probably less well known than that in the field of pure mathematics, a competent analysis of the "Mechanica" would have been valuable. Unfortunately, Dr. Scott is not equipped for the task, as is shown clearly (p. 121) in the matter of the centre of percussion and centre of oscillation, where any point at issue with Huygens is completely obscured. It is useless to pursue the subject of the development of dynamics from Galileo to Newton and the part of Wallis therein. With misguided and irritating pedantry the author always uses the name Galilei; has it become wrong to speak of Dante?

An instance of the injustice done to Wallis by lack of knowledge may be found in the disparagement of his astronomical knowledge because he accepted Flamsteed's parallax of Polaris. Naturally he was no expert, and it was not for the Savilian professor of geometry to suspect an error on the part of the Astronomer Royal. The gibe also appears in Miss Clerke's article in the "Dictionary of National Biography". The incident shows how in similar circumstances a great man, Bradley, made the discovery of aberration, while a lesser man, Flamsteed, merely made a mistake. But it belongs to the life of Flamsteed; so far as Wallis is concerned, it is practically irrelevant.

Another incident is mentioned by Miss Clerke, and it is to be regretted that the details are not recorded in this book, for it is perhaps the finest

scientific hoax ever perpetrated. Huygens announced the discovery of Titan by a cryptogram in 1655. But Wallis had anticipated this by a similar announcement so ingeniously constructed that after the event Huygens was led to believe that the satellite of Saturn had been observed in England at an earlier date. The true facts were disclosed in 1659. The deception may have been cruel, but it seems to have been effective in putting an end to a silly practice. It is a pity that Wallis was not equally successful in bringing to a close that other unmitigated nuisance, the challenge problem.

In an appendix a sort of "Who's Who" is given of the scientific men of the period. The value of a compilation of this kind depends entirely on its accuracy. Now Harriot, though a remarkable man certainly, did not live to the age of 120 years. He died in 1621, not 1681. This is a mere misprint. But the confusion between the works of Kepler can scarcely be explained in the same way. Nor is the list of contemporaries complete. Since the theory of equations plays so great a part in the text, the absence of Tschirnhausen can scarcely escape notice.

The specimen pages reproduced from Wallis and various authors of the period are of great interest. But in a work of this kind a complete bibliography is to be expected as a matter of course. It is emphatically not enough to copy out the contents of the Oxford collected edition (1693-99).

The author's industry is attested by the references given at the foot of nearly every page. The life of John Wallis is a fine subject but a very difficult one. It is not suited to the pen of one whose whole horizon is evidently bounded by the work of Newton.

(4) The name of F. X. Freiherr von Zach is chiefly known to astronomers as that of the founder and first editor (1800-7) of the *Monatliche Correspondenz*, a useful medium for the communication of astronomical intelligence. Strangely enough, there is an important link between him and one whose name has already obtruded itself in the preceding notices. For it was on a visit to Lord Egremont at Petworth House in 1784 that he discovered the scientific papers left by Thomas Harriot, and it is from his account in the *Berliner Jahrbuch* (1785, 1793) that the nature of Harriot's astronomical activity became known. This ranks Harriot as an astronomer in the same class with Galileo; and, be it remembered, this was one who had been to America and returned and written a remarkable book about it before the Armada. All things considered, the reputation of Harriot need depend little on a precise valuation of the merits of his "Praxis".

Father M. A. David was director of the Prague Observatory from 1800 until 1836, having been

connected with the institution for fifteen years previously. His first meeting with Zach took place at Karlsbad in 1789, the second and last at Gotha in 1801. From the correspondence which was carried on until 1805, when friendly relations were clearly broken off, sixty-two letters from Zach have been preserved at Prague and are now published. The nine additional letters of his successor Lindenau are of less interest. As David's replies have been lost, the value of the material lies chiefly in the light thrown on the character of Zach, who in that period of fourteen years shows himself as an admirable correspondent, keenly interested in all that was going on in the astronomical world, but chiefly in geodetic operations.

Born in 1754, Zach was educated at Paris, where he met Laplace and Lalande. In 1783 he was living in London, where he made contact with Maskelyne and Herschel and also the English instrument makers of the day. With the latter he had extensive dealings afterwards, both on his own account and for others. In 1786, under the Duke of Saxe-Gotha, he equipped a new observatory and directed it until the death of the Duke in 1804.

Of Zach's activity at that period there can be no doubt. But his voluminous correspondence with astronomers, his duties as editor and his active interest in geodetic operations must have interfered seriously with any astronomical work. It is therefore not altogether surprising to learn that

after his resignation the observatory was found to be in a deplorable state. Indeed, after the Duke's death, Zach disappears to all intents and purposes from the world of astronomy, though he still found occupation in editing a journal.

Had the Freiherr v. Zach been an indifferent musician or poet, instead of an indifferent astronomer, his later career would have provided material for a romantic biography. He attached himself as Hofmeister to the Dowager Duchess, the widow of his patron, and accompanied her in her travels in France and Italy until her death in 1827. According to one account he married the lady. Five years after the death of the Duchess, Zach fell a victim to cholera in Paris.

Zach's friend and successor, B. A. von Lindenau, did not remain permanently attached to astronomy, but embarked on a political career which earned for him a reputation in Saxony as a statesman and philanthropist. He died in 1864.

The present collection of Zach's letters show him to have been not only an admirable scientific correspondent but also a most efficient medium for the forwarding of astronomical literature and arranging for the supply of instruments. They abound in allusions to the astronomers living at the end of the eighteenth century and they convey much information about the equipment of observatories at that time and, more particularly, about portable instruments for use in the field. H. C. PLUMMER.

Petroleum Literature

(1) *The Principles and Practice of Lubrication: a Manual for Petroleum Technologists, Students, Engineers, Oil Salesmen, etc.* By Prof. Alfred W. Nash and Dr. A. R. Bowen. Second edition, revised. Pp. xi + 345 + 28 plates. (London: Chapman and Hall, Ltd., 1937.) 18s. net.

(2) *The Principles of Motor Fuel Preparation and Application* By Prof. Alfred W. Nash and Dr. Donald A. Howes. Vol. 1. Second edition, revised and enlarged. Pp. xiv + 628 + 15 plates. (London: Chapman and Hall, Ltd., 1938.) 36s. net.

(3) *The Chemistry of Petroleum Derivatives* By Carleton Ellis. Vol. 2. Pp. 1464. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1937.) £5 net.

THE oil industry is one of the most important of any, and it is in keeping with its rapid expansion that it has an ever-extending literature of the first rank which, perhaps more than any

other, is continually being revised and kept up to date. In Great Britain we are fortunate in that Prof. A. W. Nash of Birmingham is willing to devote a large portion of his time to making his knowledge available to his students and contemporaries.

(1 and 2) Prof. Nash's book on lubrication, which has now become an exact science, has been brought up to date in a second edition eight years after its first appearance. More recently the second edition of his "Motor Fuel" has appeared, in this instance after only four years. Even in this short space of time much has had to be added, in particular a section dealing with polymerization and pyrolysis. These processes have enabled superior grade petrols or gasolines, as they are termed in America, to be produced synthetically from both natural and cracked hydrocarbon gases, thereby adding to the total yield of motor-car fuel which can be obtained from a ton of crude oil and so contributing to the conservation of this material. Such high-grade fuels have a direct

connexion with the performance of the modern engine, particularly in aeroplanes at high speeds. Indeed, some of the more daring experts predict the advent of a day when crude oil is first cracked to gas and the fragments reunited in a controlled manner to form high-grade products.

(3) In the United States, Carleton Ellis is an equally prolific writer, and vol. 2 of his "Chemistry of Petroleum Derivatives" appears four years after vol. 1. It is very long and contains a wealth of information in fifty-four chapters. With the industry greedy to make use of his discoveries, the chemist has achieved much in this field and it

would make an interesting task, far too lengthy to undertake here, to contrast the state of knowledge relating to the hydrocarbons forty years ago and to-day. It is possible even to suggest that Mr. Henry Ford, when he made the automobile available to everyone, unknowingly inspired even more chemical research than engineering development. To-day this is going on faster than ever, partly because there is no knowing which particular line of work may become a major technical development in the near future.

Such a book as this saves hundreds of hours of valuable time to the worker, and in this way accelerates the tempo of new work.

Microchemistry

(1) Qualitative Analyse mit Hilfe von Tüpfelreaktionen:

Theoretische Grundlagen, Praktische Ausführung und Anwendung. Von Dr. Fritz Feigl. Dritte neu bearbeitete Auflage. Pp. xii + 554. (Leipzig: Akademische Verlagsgesellschaft, m.b.H., 1938.) 30 gold marks.

(2) An Introduction to Microchemical Methods: for Senior Students of Chemistry. By Dr. Cecil L. Wilson. Pp. xi + 196. (London: Methuen and Co., Ltd., 1938.) 7s. 6d. net.

(1) **T**HE popularity of spot methods of analysis is evident not only from the increasing number of text-books dealing with this section of microchemistry but, more particularly, from the fact that in the course of seven years three editions of Prof. Feigl's authoritative treatise have been called for, while, in addition, there have been English and Russian translations. To each edition subsequent to the first there have been made numerous additions, and this third German edition contains many new tests, some of which have not hitherto been published. The theoretical part of the book has also been enlarged, not only by the amplification of many of the original chapters, but also by the inclusion of chapters dealing with fluorescent analysis and spot tests, and the influence of substitution on solubility.

In the practical section, drop reactions are given for the first time for germanium, platinum, indium, gallium, lithium and caesium, and for hydrazoic acid, while the chapter on the systematic investigation of inorganic mixtures has been expanded by the inclusion of preliminary tests for the detection of anions. To the organic compounds and radicals

dealt with in the second edition (reviewed in *NATURE*, 136, 89; 1935), there have now been added schemes for the detection of formaldehyde, methyl alcohol, *p*-phenylenediamine, phosgene, aromatic *m*-nitro compounds, oximes and hydroxamic acids, acid amides and nitriles, pyrrole derivatives, and α -amino acids. A number of new applications of spot tests is also given.

In order that the size of the book should not be unduly increased, space has been saved by omitting the preparation of reagents and by mentioning only briefly those tests which are less sensitive or well known.

(2) This interesting, although somewhat ambitious text-book, is meant to serve as an introduction to microchemistry, and is intended primarily for senior students in chemistry. With the exception of quantitative organic analysis, it treats of all the usual sections of the new science, such as chemical microscopy, the use of the polarizing microscope, spot tests, inorganic qualitative and quantitative analysis, organic qualitative analysis, colorimetry, photomicrography, and spectroscopy. It is obvious that in such a small compass the author can be but briefly descriptive, that practically all theoretical treatment must be omitted, and that the number of examples provided must be limited. Nevertheless, enough is given to illustrate the various methods, and to enable the student to acquire sufficient confidence and skill to permit him to make effective use of more advanced text-books.

Although much is compressed into a little space, the monograph is clearly written, and is easy to read, while the text is effectively illustrated by numerous figures and photomicrographs.

G. R. DAVIES.

Vergleichende Morphologie der höheren Pflanzen
 Von Prof. Dr. Wilhelm Troll. Band 1: Vegetationsorgane. Teil 1, Lieferung 3. Pp. xii+509-955.
 (Berlin: Gebrüder Borntraeger, 1937.) 39.50 gold marks.

THE third "Lieferung" of the first part continues the large subject of branching in ferns and seed-plants. Axillary branching is discussed, as also the exceptions thereto, such as epiphyllous displacement of the lateral branch, and dichotomy in palms. Accessory or supernumerary axillary shoots and their independent origin from the meristem of the axil-tissue are described. The section on the structure of lateral shoots is replete with interesting and varied examples.

Following this is an engaging account of sub-cotyledonary shoot-formation, instances of which are given in *Linum*, *Linaria*, *Ocyclamen*, *Orobancha*, *Euphorbia*, etc. In the parasitic families of *Orobanchaceae*, *Balanophoraceae* and *Rafflesiaceae* hypocotyledonary and root-shoots entirely replace from the beginning the main shoot, which never exists at all in their life-history. There is a lengthy and well-illustrated chapter on the influence of symmetry conditions on branching—a very wide subject, and of far-reaching importance.

The next section deals with the orthotropic and plagiotropic growth of shoots.

A valuable and interesting section is that headed "Storage Shoots". It treats of (1) the origin and structure of rhizomes; (2) bulbs; (3) hypocotyledonary tubers and allied structures: amongst these are described the remarkable forms occurring in the *Dioscoreaceae*, some of which are rhizomes, others root tubers, and still others shoot tubers; and finally (4) rhizome and stolon tubers exemplified, for example, in *Stachys tuberifera*, *Trientalis europaea*, *Crepis bulbosa*, *Arum maculatum*, *Orcus*, etc.

Section 7 deals with twining and tendril-forming shoots; and no one could wish for a more thorough treatment of this subject.

The final section provides a most interesting and instructive account of the form-relationships of *stem-succulent* plants.

The whole "Lieferung" is splendidly illustrated with photographs and drawings. W. O. WORSDELL.

Handbuch der Anorganischen Chemie

In vier Bänden. Herausgegeben von Prof. Dr. R. Abegg, Dr. Fr. Auerbach und Dr. I. Koppel. Band 4, Abteilung 3: Die Elemente der achten Gruppe des periodischen Systems. Teil 2: Eisen und seine Verbindungen. A. Lieferung 3: Legierungen und Verbindungen des Eisens mit H, B, Si, P, As, Sb, Bi, S, Se, Te. Von Dr. I. Koppel. Pp. viii+559-723. (Leipzig: S. Hirzel, 1938.) 20 gold marks.

THE chemistry of such a widely used and technically important element as iron is so extensive that it is not surprising that the editors of this well-known "Handbuch" have found it necessary to divide the comprehensive study of iron and its compounds into more than one book.

It can be seen from the title that the volume under review constitutes the second part of this monograph on iron and includes the combinations of this element with some ten non-metals and metalloids. It possesses all the desirable features of comprehensiveness and simplicity in the arrangement of the subject matter, which have made Abegg justly popular among chemists. The thoroughness with which the literature has been covered may be gauged from the fact that there are references from 1718 up to the middle of 1937, and, what is more, they can be found without difficulty.

Workers on iron will find this book invaluable within the scope of the title, and it should be on the shelves of every reference library dealing with chemical or metallurgical topics. It is printed in clear type on good paper.

Beiträge zur Mineralogie von Japan
 Begründet von T. Wada. Neue Folge, II. Herausgegeben von T. Ito. Pp. xii+168+9 plates. (Tokyo, 1937.) n.p.

PROF. T. ITO, of the Mineralogical Institute of Tokyo, is continuing the excellent work begun by the late Prof. T. Wada by publishing the results of the investigation of the minerals and rocks of Japan and its dependencies. The present part is devoted to the composite sill which intrudes into the Tertiary formations near Kergan in north-eastern Korea. It is styled a sill, although the shape owing to the effect of the interposing rocks is more varied than is ordinarily understood by the term. The core consists of a syenitic rock, above and below which is a compact syenite-dolerite.

A full and careful description is given of the rocks and the various minerals composing or associated with them. The investigation includes the study of X-ray powder diagrams of goethite and of certain pyroxenes, the diagrams being reproduced on three of the plates. The frontispiece takes the form of a plate, on which are reproduced in colour a specimen of goethite in natural size and of specimens of goethite and aegirine as seen under the microscope.

The text is in Japanese, but the book can be understood without a knowledge of this language, since the crystal forms and angular measurements are expressed in the customary manner and a good abstract in English is incorporated at the end. The alternative title-page is still retained in German.

Die Chromatographische Adsorptions-methode:
 Grundlagen, Methodik, Anwendungen. Von Prof. Dr. L. Zechmeister und Dr. L. v. Cholnoky. Zweite wesentlich erweiterte Auflage. Pp. xiii+354. (Wien und Berlin: Julius Springer, 1938.) 19.80 gold marks.

IN twenty months this book, of which the first edition was reviewed in NATURE at some length (140, 48; 1937), has gained 125 pages—an increase of fifty per cent. This remarkable growth-rate is testimony not only to the importance of the subject, but also to the author's admirable exposition thereof. It should augur well for the success of the English edition now in preparation. A. L. B.

Recent Developments in Cyclotron Technique

By Dr. W. B. Mann, Imperial College, London

AT Berkeley, California, the first cyclotron to be built for the purpose of medical and biological research is nearing completion. In Great Britain it still remains a matter for debate as to whether the immediate expenditure on the construction of a medical cyclotron would be justified or whether it would, perhaps, be better policy to await the outcome of the research which has already been started in Berkeley.

The underlying principles of the cyclotron have already been adequately described in these columns by Prof. J. Chadwick (*NATURE*, 142, 630; 1938). It will therefore be the purpose of this article to try to enumerate some of the developments that have been made during the last few months.

Perhaps the most important of these developments has been the completion in Berkeley of an investigation into the possibility of using the very large currents circulating within the 'dees' of the cyclotron for the purpose of preparing artificially radioactive material. In the preparation of radioactive substances, either for therapeutic or for indicator purposes, it is important to obtain large yields. An increase in yield may be achieved in two ways: by using higher intensities, or, in the case of proton or deuteron bombardment, by the use of particles of higher energy.

In the latter case we are tacitly accepting the fact that the energies available are still considerably less than the energy corresponding to the top of the potential barrier of the bombarded nucleus, and that the yield is still rapidly increasing with increasing energy of the bombarding particle.

The purpose of the new cyclotron at Berkeley is to increase both the current and the energy of the emerging beam. With this cyclotron it is hoped to obtain deuterons with energies corresponding to accelerations in the neighbourhood of fifteen million electron volts. In the meantime, however, every effort is being made to increase the yields of radioactive products by using the large currents available within the 'dees' of the present cyclotron at Berkeley.

Prof. E. O. Lawrence had suspected the existence of large currents of circulating ions within the 'dees' and these suspicions were confirmed by the observations of R. R. Wilson, of the Radiation Laboratory, which were reported last August at the meeting at San Diego of the American Physical Society. It was found that in the case of deuterons, the ion current circulating within the 'dees' was of

the order of one milliamperere, the energies of the deuterons ranging from 6 to 9 million electron volts. Only some 10 per cent of the available current was, however, being withdrawn by the deflector and used in the target chamber.

A paper published by R. R. Wilson and M. D. Kamen last December describes the technique whereby these large currents of high-energy ions may be utilized in the preparation of radioactive phosphorus and iron. Previously, as has been described by F. N. D. Kurie, radioactive phosphorus had been prepared by bombardment of red phosphorus in an atmosphere of helium, the bombardment chamber being separated from the vacuum chamber of the cyclotron by means of a thin iron window, which was itself rendered radioactive by the deuterons passing through it. Thus both radioactive phosphorus for therapeutic purposes and radioactive iron for indicator experiments were produced simultaneously.

Wilson and Kamen have used instead iron phosphide for bombardment and have inserted this, mounted upon a water-cooled copper plate, between the 'dees', through the south window of the Berkeley cyclotron; the design and disposition of the Berkeley cyclotron having become something of a prototype, no further explanation with regard to the point of the compass is, perhaps, necessary. They found that they were able to obtain currents of incident deuterons of 150–200 microamperes, and at the same time the beam drawn by the deflector from the 'dees' and arriving in the target chamber was decreased by only 10 per cent. By inserting the target farther between the 'dees', incident ion currents of more than six hundred microamperes were obtained.

Using this technique, Wilson and Kamen have succeeded in obtaining ten millicuries of radioactive phosphorus in the course of a day.

A further advantage of the use of internal targets is derived from the fact that the ion current density is higher within the 'dees', and thus for a given yield it is necessary to expose a much smaller area of target than in the case of bombardment in the target chamber. Thus the ratio of radioactive to inactive phosphorus is enhanced, a definite advantage for therapeutic purposes where it may not be desirable to administer large quantities of inactive phosphorus. Wilson and Kamen are confident that specimens of several millicuries per milligram of phosphorus can easily be prepared.

The possibility of using neutron irradiation for the treatment of cancer has been one which has long attracted the attention of Prof. Lawrence, and two years ago, in collaboration with his brother, Dr. John Lawrence, and Mr. P. C. Aebersold, he published the results of a comparative study of the effects of X-rays and neutrons upon healthy and malignant tissue. From these it appeared that, for a given lethal dose with respect to normal healthy tissue, neutrons were quite as effective as X-rays in destroying malignant cells and indeed might even be more efficacious to the extent of some 20-30 per cent. These experiments were carried out on mice, using transplanted sarcoma tumours. The results were sufficiently encouraging for experiments to be planned on a clinical scale, and the new cyclotron was designed with this in view.

Before such experiments could be carried out, however, it would be necessary to obtain a collimated beam of fast neutrons which could be directed upon that locality which it was desired to irradiate. The satisfactory solution of this problem has been reported by Aebersold and Prof. Gladys A. Anslow at the New York meeting of the American Physical Society last February. Essentially, the fast neutron beam was obtained by means of an air channel through a water tank, the depth of water being sufficient to reduce the velocities of the neutrons and also appreciably to absorb them. A certain intensity of unabsorbed slow neutrons will, however, not be detrimental, since the biological action of neutrons is chiefly by reason of the heavy ionization produced by the proton recoils from fast neutrons. In order to eliminate gamma-radiation originating in both the water tank and the source, Aebersold and Anslow surrounded their channel and covered the outside walls of the water tank with lead and filtered the beam of fast neutrons through a slab of the same material. With the beam so obtained clinical treatment has already begun in Berkeley.

Further recent developments in cyclotron technique include an important contribution by L. W. Alvarez who, very ingeniously, by modulation of the cyclotron beam, has been able to produce monochromatic beams of neutrons of thermal energies. The method is essentially similar to that which has been developed independently by G. E. F. Fertel, P. B. Moon, G. P. Thomson and C. E. Wynn-Williams, and which was the subject of a recent letter in *NATURE* (142, 829; 1938). Bursts of neutrons were produced, in the former case by modulation of the radio-frequency input to the cyclotron, and in the latter by modulation of the current in the ion source of a 300 kv. deuteron discharge tube. The resolution which has been obtained by Alvarez is not, however, so sharp

as in the experiments with the discharge tube, a difference which can probably be ascribed to the fact that, in the case of the cyclotron, instead of a short sharp pulse of voltage being applied to the plates of the oscillator, modulation was effected by the use of 60-cycle A.C. after half-wave rectification. Under these conditions Alvarez reports that the cyclotron beam was incident upon the target for 25-30 per cent of each cycle, whereas in the case of the experiments of Fertel, Moon, Thomson and Wynn-Williams, the duration of the neutron pulse was limited to only 10 per cent of the cycle.

Alvarez has, however, quite adequately demonstrated the potentialities of his method, and any increase in resolution is probably merely a matter of experimental refinement if, and when, it may be required.

A question which has aroused some interest, although it has as yet little practical significance, is the difficulty which will arise when the energies of the ions produced in the cyclotron shall be so great as to cause a breakdown in the resonance condition, due to the relativistic increase in mass of the ions at velocities comparable with that of light. A deuteron having an energy of fifteen million electron volts or an alpha-particle having twice that energy will be travelling with velocities of a little more than a tenth of the velocity of light. The consequent increase in mass of about one per cent, due to relativity, will cause an increase in the time taken for a particle to describe the semi-circular path within the 'dees'. It will therefore tend to lag behind the electric field and will be lost from the beam.

By effecting a suitable increase in the magnetic field at large radii, the path of the ion can be decreased to such an extent that it will arrive in phase with the electric field, but such a magnetic field would necessarily have a defocusing effect upon the beam. In a recent paper, L. H. Thomas has suggested that the magnetic field should be made, not only to increase with radius, but also to vary periodically along the path of the ion. This latter variation in the magnetic field introduces a further focusing effect which will partially counteract the defocusing effect due to the increase of magnetic field at large radii, necessary to compensate for the relativistic increase in mass of the ions. Thomas shows that by this expedient it will be possible to attain to energies where the relativity effect is already appreciable.

In deciding between the relative merits of radium, X-rays and a cyclotron for medical purposes, there is a natural tendency to count the cost and to calculate possible yields of radioactive materials in terms of interest on capital expended. Already sources of radioactive sodium have been prepared

in Berkeley with a strength of several hundred millicuries using the ordinary technique of bombardment with deuterons in the target chamber; radioactive sodium, in the process of decaying to magnesium in the ground state, emits a gamma-ray of such energy as may dispose of the need for radium for some purposes. This, with the results of the investigations into the yields using internal targets, and the possibilities of neutron irradiation of malignant tissue, should be an added stimulus to those who are in favour of the immediate construction of a cyclotron for medical purposes in Great Britain, believing that active research alone, with the most recent techniques available, is the necessary preliminary to any further progress in the treatment of cancer.

There are now some twenty-six cyclotrons, either operating or under construction, in various parts of the world. At Berkeley there are two cyclotrons, one belonging to each of these two categories. In addition, cyclotrons are running, or

have been running, at the following places: Ann Arbor, Michigan; Cambridge; Copenhagen; Ithaca, New York (Cornell); Leningrad; Princeton; New York (Columbia); Rochester, New York; Swarthmore, Pennsylvania (The Bartol Foundation of the Franklin Institute); Tokyo; Urbana, Illinois.

Cyclotrons are also under construction at Birmingham; Bloomington, Indiana; Cambridge, Massachusetts (Harvard University and Massachusetts Institute of Technology); Chicago; Columbus, Ohio; Lafayette, Indiana (Purdue); Liverpool; Montreal (McGill); New Haven, Connecticut (Yale); Paris; Seattle, Washington; Stockholm.

The conclusion of this article on the cyclotron would, indeed, be inappropriate without a tribute to Prof. Ernest Lawrence, through whose imagination and experimental skill this valuable tool has been placed in the hands of the experimental physicist.

North Rona: a North Atlantic Island*

By Dr. F. Fraser Darling

MAN has such little interest in Rona that this island of less than half a square mile has disappeared from many maps of Scotland. It lies about forty-five miles north-east of the Butt of Lewis and north-west of Cape Wrath. The island is completely rockbound, the cliffs varying from a few feet to 355 feet in height. The continual Atlantic swell makes landing difficult and often impossible.

Rona is a northern outpost of the Hebridean hornblende gneiss intersected by several veins of pegmatite. Botanically, the island is distinct from the Hebrides. The northern end of Lewis is a vast peat bog which grows a characteristic herbage complex dominated by heather (*Calluna*). But there is no peat on Rona. The rock is covered with a thin layer of soil held together with a good turf of Yorkshire fog (*Holcus*), bents (*Agrostis*), sheeps' fescue (*Festuca*). Sedges (*Carex*) are rare on Rona, occurring only to the west of the ancient village site, where the turf has been cut for fuel hundreds of years ago. There are no permanent pools of fresh water on Rona. A well for seepage has been chiselled in the solid rock at the edge of the cliff in Poll Heallair on the south side of the island and it holds about ten gallons.

The drier rocky places are covered with a wealth of sea pink (*Statice*) and buckhorn plantain (*Plantago*); the cliff edges, heavily manured by the summer population of birds, grow luxuriant sprays of scurvy grass (*Cochlearia*), some sheep sorrel (*Rumex*) and mayweed (*Matricaria*). The village area with its lazy beds grows wild white clover (*Trifolium*) on the dry banks of conserved soil, and in the immediate vicinity of the ancient dwellings, silverweed (*Potentilla*) almost crowds out everything else. There is no bracken, fern or spleenwort, and few of those flowers which make the northern lands gay in May and June.

The whole of Rona is washed by salt spray in winter gales, but the northern peninsula of Fianuis is often impassable under a continuous driven cloud. Only plants with a high tolerance of salt can grow there—annual poa grass (*Poa*), sea pink, sea milkwort (*Glaur*) and chickweed (*Cerastium*).

So far as we know, St. Ronan was the first human inhabitant of Rona, in the eighth century A.D. He moved to Rona from Eoropaiddh at the north end of Lewis and adopted the name of the island as his own. Thus we gather that Rona, *ron-y*, has been the island of seals for a very long period. The cell of St. Ronan still remains in a fair state of preservation, and I have done some

* Substance of a Friday evening discourse delivered at the Royal Institution on January 20.

FIG. 1. CHAPEL (LEFT) AND CELL OF ST. ROMAN (RIGHT) SHOWING RESTORATION OF SOUTH WALL.

excavation and slight restoration (Fig. 1). The east and west walls of the cell inside are almost perpendicular, but the longer north and south walls slope inwards rapidly, and at a height of more than 11 ft. are 18 in. apart. Rectangular slabs of gneiss are placed across the top to finish the roof. The length and breadth of the cell at floor-level are 11 ft. 6 in. and 8 ft. Earth and stones were banked high round the outside of the north, east and south walls so that the building was practically underground.

The outside west wall became the east inside wall of a chapel which was built some time after Ronan's cell. This building, also in dry-stone but of poorer workmanship, is 14 ft. 8 in. by 8 ft. 3 in. and forms in effect a nave to the cell as chancel, though it is doubtful whether the two buildings were used conjointly as such. A block of masonry was laid bare on each side of the doorway into the cell and at the foot of these piers, which were taken to be the supports for the wooden altar in the later chapel (described by Martin Martin in 1703), a rough paving was found leading into the cell. The paving of the cell has been completely cleared at the eastern end, revealing an altar of well-built masonry 2 ft. 6 in. high, 3 ft. broad and 2 ft. 3 in. deep. A polished stone, rather smaller than a man's fist, was found at the foot of this altar and it appears to be of the same rock as Iona green marble, a rock entirely foreign to North Rona.

The first written mention of Rona and its people was made in 1549 by Sir Donald Monro, High Dean of the Isles, and later we read from Martin Martin of the life of the five families: "They covet no wealth, being fully content and satisfied

with food and raiment; though at the same time they are very precise in the matter of property among themselves; . . . they take their surnames from the colour of the sky, rain-bow and clouds". A plague of rats came ashore from a wrecked ship between 1680 and 1690 and ate up the whole sustenance of the people, who then starved to death. The half-underground dwellings remain and it is evident they were entered by low and devious passages which would baffle the wind, which is an all-important factor in life on Rona. Several quern stones were found about these dwellings and two fragments of stone vessels.

Rona is an important sea-bird station. The guillemot population is approximately 12,500 pairs; kittiwakes are equally numerous and the puffins are countless. There

Fig. 2.

BRIDLED GUILLEMOT WITH PLAIN MATE.
13.2 per cent of common guillemots on North Rona are bridled.

are about 750 pairs of razorbills and 600 pairs of fulmar petrels. A population of at least 500 pairs of great black-backed gulls is predatory on the puffins. Storm petrels are numerous, and Rona is one of the three British breeding stations of Leach's fork-tailed petrels. Arctic terns and black guillemots also breed on the island. There is a resident flock of 300-400 starlings. Many interesting migrants visit Rona on their spring and autumn passage—flocks of white wagtails, of waders such as knots, sanderlings, dunlins and redshanks. Turnstones may be resident. There are such occasional visitors as the

corn is now largely fed to the cattle in the straw.

The annual association of the seals with the land for reproductive purposes is their time of greatest danger, and the social system of the animals has become finely adapted for lessening this danger of the sea's edge. The seals are migrating to the island throughout August, but on arrival they do not come farther ashore than outlying skerries and ledges at the foot of the cliffs. Behaviour alters early in September, when mature bulls come on to the main mass of the island, as far as 300 yards inland, and lie quiet and alone

Fig. 3.

ATLANTIC GREY SEALS ON A LEDGE AT THE EDGE OF THE SURF.

green sandpiper, spotted redshank, short-eared owl, buzzard, hen harrier, woodcock and great snipe. Although the island has a good turf, neither grey lag nor barnacle geese winter there.

North Rona is the headquarters of the Atlantic grey seal, *Halichoerus gryphus* (Fig. 3). Protection by law has helped the species to recover from the low numbers brought about by the careless hunting in the nineteenth century. There is also the fact that the advent of rubber for sea boots and paraffin for light have made it unnecessary for the Hebridean to use sealskin and blubber. Crofters' cattle are now better fed, and no longer receive seal oil in the winter since threshing of the peoples' own oats has declined and the

by small pools of brackish water. Bulls in adjacent territories make no attempt to impinge on each other's ground, but throughout the breeding season there is a traffic of bulls coming up from a neutral reservoir at the sea's edge, and these challenge the bulls in possession. The winner stays and the loser returns to the neutral ground, where all challenging behaviour is laid aside.

Cows come ashore about a week later than the bulls and, by the cows' freedom to move where they will, it appears that the territories of the bulls are most decidedly entities of space and not of numbers of cows within that space. The matings take place 11-14 days after the birth of the calves, so the bulls have been ashore then at least three

weeks without any cows having been in season. The maiden cows and a few old cows without calves collect on the surf-ringed skerry of Loba Sgeir and mate there with young bulls. It was exceptionally interesting to observe that all these animals lay cheek by jowl without any apparent expression of territorial behaviour. The young stock does not come inland.

After the breeding season a large proportion of the adult stock gathered on Loba Sgeir and lay quiet there until they had moulted their coats. They leave Rona then to feed about the Hebridean coasts until the next season.

The Atlantic grey seal calf is thin when born but puts on fat at a very rapid rate. Its fluffy white coat begins to be shed at a fortnight old

and it is then that lactation in the cow rapidly declines and maternal care ceases. The calves face starvation until they reach the sea, and from a cliff-bound island that journey is a perilous one.

The occupation of the northern peninsula of Rona by the seals affects the vegetative complex and creates a favourable environment for Chironomid larvae. Thus the island is a fruitful port of call for migrant birds and a place of immense consequence to many others. In any attempt to conserve our country's wild life we should not forget the little islands, for they have a value as sanctuaries far beyond that which their size would indicate. Rona, where man has failed to survive, is one of the great cities of this earth.

Scientific Approach to Milk Policy

MANY members of the British Association for the Advancement of Science have been feeling during the past three or four years that more efficient machinery should be devised by the Association for the consideration of the effects on society of scientific developments and discoveries, and for the application of scientific methods to social ends. At the Cambridge meeting of the Association in August last, it was decided to constitute a new Division of the Association to be concerned with social and international relations of science, and Sir Richard Gregory was elected the first chairman. It was later decided that the Division should hold meetings, at times intermediate between those of the normal annual meetings of the Association, at different centres in Great Britain and elsewhere.

The Nutrition Sub-Committee of the new Division has been the first to get off the mark, and, at the University of Reading on March 28, held a one-day conference on milk, in its nutritional and allied aspects. It is a commonplace that the handling of the milk question is the most awkward problem in any long-range policy concerned with improvement either in general health or in agriculture, and the boldness of the young Division in firmly grasping this important domestic nettle at its first meeting is a good augury for its future activities. In view of the trying weather, the attendance (about 180 were present at the main session) cannot be regarded as other than satisfactory.

The day began with a visit of the more weather-resistant members to the National Institute for Research in Dairying at Shinfield near Reading.

Here the party was shown, by the Director and staff, experimental work on various *ad hoc* dairy industry questions, and also on some of the more fundamental problems of dairy science. Amongst the investigations described were those on the protein requirements of dairy cattle, on new methods for the pasteurization of milk, on the effect of various types of commercial processing on the nutritive value of milk, on the causes of low compositional quality in milk, and on the hormonal control of lactation. The new chemical and physiological laboratories now rapidly approaching completion, and the completely rebuilt dairy machinery testing centre were inspected, and the memorial library and the recently founded Imperial Bureau of Dairy Science visited.

After lunching at the University, members met for the afternoon session in the Great Hall, where the Vice-Chancellor (Sir Franklin Sibly) welcomed the Association on behalf of the University. The chair was taken by Sir Richard Gregory, who introduced the three principal speakers, Dr. Harriette Chick, Prof. J. C. Drummond and Dr. A. W. Scott. The papers given by these three dove-tailed so closely into one another that it is more convenient in this brief report to deal with them together.

The factual basis for the emphasis which has been laid on the importance of milk in the national dietary was re-described, and the food value of milk products, for example skim milk, was discussed. Despite its food value, milk is rather an awkward material to handle and distribute, and a potentially dangerous material for the consumer if it is not properly produced and processed. Whilst Great

Britain lingers rather far behind several other countries (such as Sweden, Switzerland, Norway, the United States), in liquid milk consumption per head, yet when dairy products such as butter, cheese, cream, dried milk, etc., are taken into account at their liquid milk equivalent, our consumption of liquid milk plus milk products puts us in a high position on the list, the consumption having increased from 322 kgm. per head per year in 1925-29, and 403 kgm. in 1930-31, to 548 kgm. in 1934. The dietetic value of milk is practically unaltered by properly controlled commercial pasteurization, and little affected even by sterilization and drying. This recent conclusion is the result of carefully controlled feeding and other experiments carried out at the National Institute for Research in Dairying and at the Rowett Institute, and also in elementary schools in England during the past four years, under the auspices of the Milk Nutrition Committee (chairman, Lord Astor). These findings and those obtained by other responsible investigators have finally disposed of the fallacy that commercial methods of pasteurization seriously damage the food value of milk. Kon has shown that one of the most labile constituents of milk, vitamin C, is, in milk, actually more sensitive to light than to heat, though milk is, in any event, a poor source of this vitamin. In view of the potential danger of drinking raw milk, exemplified from the health records of past years, which show how much ill-health is directly traceable to an infected milk supply, it was stated that no good scientific reason exists why the pasteurization of all milk for liquid consumption should not now be enforced.

The implications of such a policy were dealt with in some detail. A very large proportion of the milk supply of Great Britain is already heat-treated, but frequently inefficiently heat-treated, so that disease organisms are not completely destroyed, though the keeping quality of the milk may be improved. One of the advantages of compulsory pasteurization would be that supervision of commercial heat-treatment could be made much more efficient than at present, particularly now that the phosphatase test is available. Objections to compulsory pasteurization on the grounds that it would lessen the stimulus to the eradication of disease in dairy herds, or that it would cause farmers to relax their efforts towards clean milk production, or that it would put the whole industry in the hands of the large distributing combines, were stated to be without foundation. With reference to this last objection the control of the industry is now, in fact, in the hands of the largest possible combines—the producers' marketing boards.

Following the principal speakers, there was a short discussion. One of the most important

points in favour of compulsory pasteurization was made during the discussion—namely, that it would actually help the producer by increasing public confidence, and the confidence of medical men (who in matters of nutrition are frequently the mentors of the public) in the safety of the milk supply. A rather loosely worded resolution was passed by the divisional meeting, for consideration by the Council of the British Association, recommending that pasteurization of all milk to be sold in their areas should be enforced by all authorities dealing with a population of 20,000 or above.

It would perhaps be an exaggeration to say that this resolution is battering at an open door. It is no secret that the big producers' organizations in Great Britain are not opposed to compulsory pasteurization at least as applied to the large municipal areas, with a stipulation that a supply of raw tuberculin-tested milk should be available for those individuals who really prefer raw milk. The Government too, in 1938, accepted the principle of compulsory pasteurization and had incorporated it, with certain safeguards, in the very comprehensive and well-thought-out Milk Industry Bill, which was withdrawn a few months ago. That the withdrawal was on account of the compulsory pasteurization clauses seems highly unlikely.

Quite apart from new legislation, however, a suggestion, admittedly not novel, was made informally after the meeting which, if put into action, might greatly ameliorate the risk, from the consumer's point of view, of milk-borne disease. Heavy penalties could presumably be exacted at common law from any retailer who had sold milk which could be proved to have caused disease in the consumer; if this were done in one or two cases, it is not unreasonable to suppose that raw milk distributors themselves would feel disinclined to continue to risk not merely the consumer's health, but also their own reputation, trade and pocket, by selling unsafe milk in the future.

During the evening session, the chair was taken by Sir Daniel Hall, and two papers, one by Mr. James Mackintosh on milk production, and the other by Mr. John Cripps on milk distribution and costs were given. The main problem of increased production in Great Britain to meet a steadily increasing demand for liquid milk was stated to be, at least in the early stages of this demand, that of increasing the winter supply, which in November, December, and January is at present very close to the minimum required to cover the needs of the liquid trade.

It would be possible to even out supplies during the year by arranging for more cows to calve in autumn. Again, far better yields per cow than those obtained at present are possible in many herds by making use of knowledge already available

on feeding and management, and on methods of breeding. In urban distribution, it was pointed out that the consumer is suffering under a surfeit of retailers, many of whom could be dispensed with, and of 'services' many of which are quite superfluous with properly processed milk. If surplus retailers and these costly but unnecessary services could be dispensed with, consumer prices could be reduced. But without monopoly in some form or another, it is not easy to see how a stable scheme for effective and minimum-cost distribution could be brought about. It was suggested that, instead of further verbal discussion of hypothetical alternatives, some experiments on different types

of monopoly control, for example, municipal, co-operative, public utility, private firm, ought to be tried out under careful supervision in limited areas. But this type of experiment cannot take place without legislation.

From the events of this most interesting day, one point emerges very clearly. This Division of the British Association by its very nature cannot proceed far without becoming involved, and involved very deeply, in politics and in active social planning. While this is well understood by the officers of the Division, it seemed to be somewhat of a revelation to several of those others who attended the Reading meeting.

Obituary Notices

Miss Dorothea F. M. Pertz

DORA PERTZ, who died on March 6, a few days before reaching her eightieth birthday, was born in 1859 into a cosmopolitan, intellectual milieu, for which it would be difficult to-day to find a parallel. Her father was Dr. G. H. Pertz, a scholar of world-wide repute, and Royal Librarian in Berlin. His first wife was a brilliant Englishwoman, who counted Simondi and Lafayette among her friends. His second wife, Dora's mother, also an Englishwoman, was one of a remarkable group of sisters, the six daughters of Leonard Horner, a prominent early member of the Geological Society, and twice its president. He was evidently a man of unusual breadth of view, for though he was born at so remote a date as 1785, he was sufficiently open-minded to commend Darwin's speculations in his last address to the Geological Society in 1861. Horner's eldest daughter was married to Sir Charles Lyell, and his second daughter to Sir Charles J. F. Bunbury, a botanist, who, under Lyell's influence, turned his attention to fossil plants.

Among the Horners, scientific enthusiasm was by no means confined to the man. Dora Pertz's grandmother helped her husband with his rock collections, and when the meetings of the Geological Society were first thrown open to women visitors, Dora's aunts, Lady Lyell and her sisters, were constant in their attendance, though otherwise few women cared to avail themselves of this privilege. Katharine Horner, who married Lyell's brother, and eventually became the biographer of her father and her brothers-in-law, was a botanist. She published in 1870 "A Geographical Handbook of Ferns"—a highly technical catalogue dealing with the distribution of this group. Of Sir Charles Lyell, in his Harley Street period, Dora had certain childish recollections, especially of occasions when he would call a hansom cab and carry off his two small nieces for rapturous visits to the Zoo. Love of animals was throughout Dora's life a ruling passion, and her youthful memory of

visiting the Darwins at Down, centred in the joy of being allowed to caress the nose of the horse on which Charles Darwin was riding, in his cloak and broad-brimmed hat.

When her father died, Dora Pertz went with her mother and sister to live in Florence, but, after some years in Italy, the family urge towards science brought her to England in 1882, in order to enter Newnham College. Having taken honours in the Natural Sciences Tripos, she continued to work at Cambridge, doing research in plant physiology under the direction of Francis Darwin, who was then a member of the staff of the Botany School. Dora Pertz co-operated in much of his work, and also produced several independent papers. The best known of their joint memoirs is probably that "On the Artificial Production of Rhythm in Plants", published in the *Annals of Botany* of 1892. She also did some genetical work in the days when that study was just beginning at Cambridge, and collaborated with William Bateson in a paper on inheritance in *Veronica*.

After Sir Francis Darwin's retirement, Dora Pertz continued for a time to make observations; but she came to recognize that the plant physiology of the twentieth century was developing on lines widely divergent from those on which she had been educated, and that it demanded a grasp of mathematics, physics, and chemistry, which she did not possess. With characteristic clear-sightedness as to her own limitations, she desisted from attempting to do research for which her equipment was inadequate, and she sought for some other means through which she could be of use to botany. Fortunately, Dr. F. F. Blackman was able to enlist her services in cataloguing pamphlets, and in making an elaborate index of the papers of plant physiological interest in the numerous early volumes of the *Biochemische Zeitschrift* and the *Zeitschrift der physiologischen Chemie*. She completed the index up to the year 1935; the magnitude of the task may be judged

from the fact that in the *Biochemische Zeitschrift* alone she had to deal with 268 volumes. A letter of appreciation of this work from the members of the staff of the Sub-Department of Plant Physiology gave her special pleasure in her last illness. Concurrently with the work on the index, she found scope for her considerable powers of draughtsmanship in making all the illustrations for a long series of papers on floral anatomy published by her friend Miss E. R. Saunders, between the years 1923 and 1936.

Over a very long period—indeed until the failure of her health brought all activities to a close—Dora Pertz was content to give her time with complete steadiness and regularity to indexing and drawing, though these somewhat mechanical occupations could not, in the nature of things, have for her the compelling charm of her own chosen work. In her absence of personal ambition, and the disinterestedness of her desire to be serviceable to botany, Dora Pertz was true to the family tradition handed on to her by Horner, Lyell and Bunbury; she was one with them in pursuing science simply for the love of it, and in being—in the basic sense of that much mishandled word—an amateur. AGNES ARBER.

Dr. Moses Gaster

WE regret to record the death of Dr. Moses Gaster, the distinguished Jewish scholar, historian, and folklorist, formerly Chief Rabbi, which took place suddenly on March 5 at the age of eighty-two years.

Moses Gaster was born in Bucharest on September 16, 1856. He was the son of the Chevalier A. E. Gaster, and a member of a family which for long had been settled in Rumania. He graduated at the University of Bucharest and received the degree of Ph.D. from the University of Leipzig and the rabbinical diploma from the Jewish Rabbinical Seminary at Breslau. On his return to Bucharest in 1880, after a period of literary activity, he became lecturer on Rumanian language and literature at the University of Bucharest and inspector-general of schools, holding in addition other public offices; but his activities in connexion with the settlement of Jews in Palestine led to his inclusion among the Jews expelled from Rumania at this time at the instance of Russia. Dr. Gaster then settled in England, where his work as Ilchester lecturer in Greco-Slavonic languages in the University of Oxford rapidly secured him a place in the front ranks of scholarship.

Dr. Gaster was the author of a large number of works on Jewish historical subjects, as well as in the more advanced Hebrew and Rabbinical studies. As a folklorist he inevitably came to be regarded as the first authority in Great Britain on the folk-lore of Rumania; but his interest in folk-lore studies was by no means confined to either his country of origin or to his special field of Jewish scholarship. His wise counsel and ready ability in suggestion were ever at the service of his fellow workers. Among his publications may be mentioned as of special interest to students of folk-lore and comparative religion "Rumanian Bird and Beast Stories", "Studies and

Texts in Folklore, Magic, Medieval Romance, Hebrew Apocrypha, and Samaritan Archaeology", "The Samaritans", embodying the Schweich Lectures of 1925, and "The Sword of Moses" an early Jewish magical work which had been lost for a thousand years until discovered and published by him.

On the cancellation of his order of expulsion Dr Gaster paid several visits to Rumania and for a report on the English educational system, published as a Rumanian State paper, and other services he received the Rumanian Order of Merit of the First Class.

Dr. Antoine Bécclère

DR. ANTOINE LOUIS GUSTAVE BÉCLÈRE, the pioneer of medical radiology in France, died at the age of eighty-two years on February 24 in Paris, where he was born on March 17, 1856, the son of a general practitioner, and received his medical education.

Béclère qualified in 1882 with a thesis on the contagion of measles and at first took a keen interest in other infectious diseases, especially smallpox—for which in collaboration with Chambon and Ménard he introduced treatment by convalescent serum—vaccinia and syphilis. Shortly after the discovery of X-rays in 1895 he became engrossed in the study of radiodiagnosis and radiotherapy, and at his own expense fitted up a radiological laboratory at the Hôpital Tenon in 1898 and started a course of free instruction in medical radiology which he resumed in 1899 after his transfer to the Hôpital Saint Antoine and continued until his retirement in 1921.

During the Great War, Béclère was director of a radiological centre at the Val de Grâce military hospital. In addition to numerous communications to medical societies and journals, he was the author of works on "Röntgen Rays in the Diagnosis of Tuberculosis" (1899), "Röntgen Rays in the Diagnosis of Non-Tuberculous Diseases of the Chest", several articles in the treatise of medical radiology edited by Prof. Bouchard (1904), and "Röntgen Rays in the Diagnosis of Internal Diseases" (1904).

Besides being Commander of the Legion of Honour, Béclère received many well-merited distinctions. In 1928 he was elected president of the Académie de Médecine, of which he had been made a member in 1908. He was also one of the first members of the recently resuscitated Académie de Chirurgie. In 1931 he was president of the third International Congress of Radiology held in Paris, and the same year he was elected an honorary fellow of the Royal Society of Medicine. On attaining his eightieth birthday in 1936 his pupils, colleagues and friends dedicated to him a jubilee volume in which his contributions not only to radiology but also to paediatrics, experimental medicine, neurology, endocrinology, diseases of the chest, diseases of the abdomen and gynaecology formed the subjects of appreciation by well-known specialists. The journal *Strahlentherapie* also devoted a *Festschrift* to him on the same occasion. During the last years of his life, he resumed his study of vaccinia and syphilis.

J. D. ROLLESTON.

News and Views

National Service Committee for Scientific Research

THE Central Register Advisory Council of the Ministry of Labour has appointed the following Committee for Scientific Research: A. V. Hill (chairman); C. G. Darwin (mathematics); E. V. Appleton (physics); J. C. Philip (chemistry); R. V. Southwell (engineering sciences); E. B. Bailey (geology); V. H. Blackman (botany); D. M. S. Watson (zoology); A. V. Hill (physiology); W. W. C. Topley (pathology); F. C. Bartlett (psychology); Director of Scientific Research, Admiralty; Director of Scientific Research, War Office; Director of Scientific Research, Air Ministry; Department of Scientific and Industrial Research; Medical Research Council; Agricultural Research Council. Ten sub-committees for the consideration of the several subjects have been co-opted.

Broadcasting by Telephone

THE Postmaster-General announced in the House of Commons on March 30, that the Post Office is to proceed immediately with the introduction of a system of distributing broadcasting programmes over the line telephone network. This service will be additional to that of the existing relay companies, the licences of which will also be extended for a further period of ten years to December 31, 1949. The new telephone broadcasting service will be operated on the so-called 'wired wireless' or carrier-current system, which is already in use to some extent in Great Britain and other countries for ordinary line telephony; a radio frequency carrier current, with the appropriate programme modulation, will be transmitted over the telephone lines, and a complete wireless receiving set will be used at the subscriber's end of the line. Three or four alternative broadcast programmes will be provided, the selection to be carried out by adjusting the receiver, and it will be possible to use the telephone simultaneously with the reception of a broadcast programme. The new service will be restricted at first to telephone subscribers, and the question of its extension to non-subscribers will be deferred pending experience of its working. From the point of view of national defence, the new service will have the advantage over the existing broadcasting system of reduced liability to interruption or interference; it is not intended, however, that any restriction shall be placed upon the wireless broadcasting programme service at the present time. The existing relay companies transmit merely the audio frequency currents over a special line network to loud-speakers on the subscribers' premises, and the service is usually limited to a choice between two programmes provided from the relay exchange. The new licences issued to these companies will require that these exchanges shall be connected to a B.B.C. station by wire, and that in time of emergency they shall transmit any special announcements ordered by the local A.R.P. or police authorities.

H.M. Aircraft-Carrier *Ark Royal*

THE annual session of the Institution of Naval Architects, was held in the Royal Society of Arts during March 29-31. Lord Stonehaven, the president of the Institution, reviewed the events of the last year in his opening address. Sir Stanley Goodall, Director of Naval Construction for the Admiralty, then read an interesting paper describing H.M.S. *Ark Royal*, the first ship to be designed exclusively as an aircraft carrier. As it is not the function of this type of ship to fight a gun duel, its armament consists mainly of aeroplanes. The ship carries a few guns capable of both high angle and low angle fire. She has a heavily armoured deck, side-armour adequate against medium guns, and improved underwater protection. 103,000 horse-power on three shafts gave her a speed in trials of 31½ knots and special attention had been given to rapid manoeuvring. The auxiliary machinery is both electric and hydraulic. Special aircraft fittings include two catapults at the fore end of the flying deck, arresting wires at the after end for aircraft landing on it, hydraulically operated wind screens which fold down flat when necessary and three two-story lifts which take aircraft with their wings folded. Electric welding was used extensively in her construction, and this lessened her weight by 500 tons. In the discussion which followed the paper Sir George Preece, engineer-in-chief to the Navy, said that owing to the necessity for rapid manoeuvring it was found necessary to have two engineers of the watch, one for general control and one for direct supervision. The large rudder immediately abaft the centre propeller was invaluable when turning at rest. In the last cruise, 1,400 aircraft landings on deck had been made without a scratch. 'Landing on' had proved safer than driving a car on an English road.

Emergency Medical Arrangements for War-Time

PREPARATIONS for dealing with casualties in the event of war are now well advanced. The Ministry of Health has issued circulars to local and other authorities under the Air-Raid Precautions Act, 1937, indicating the organization of emergency ambulance services, and of first-aid posts (Circulars 1787 and 1789. H.M. Stationery Office. 2d. and 3d. net, respectively). An emergency Hospitals Scheme for London has also been prepared. This scheme is based on the affiliation of certain casualty hospitals in the more vulnerable areas to others in outer areas. In London this affiliation is arranged in ten sectors radiating from the centre. Each of these sectors contains voluntary and municipal hospitals of widely differing types, including the great teaching hospitals, local authority institutions, mental hospitals, specialized hospitals, cottage hospitals, and others. It is proposed that the casualty hospitals near the centre of each sector should be used so far as possible for immediate treatment only, and that the injured

should be transferred at the earliest opportunity from the centre to affiliated casualty base hospitals in the outer areas.

The Palaeontographical Society

At the annual meeting of the Palaeontographical Society held in the rooms of the Geological Society on March 31, the Council reported that the Society's ninety-first annual volume had been issued during the past year. This volume contains the first part of a new monograph on the Carboniferous Rugose Corals of Scotland by Dr. Dorothy Hill. Largely based on the extensive and oft-quoted material studied by James Thomson and afterwards disorganized by the fire in the Kilmarnock Museum in 1909, this monograph introduces considerable simplification in systematic nomenclature. Further instalments of the monographs on Cambrian trilobites by Mr. P. Lake and on corallian ammonites by Dr. W. J. Arkell are also included in this volume. The work of the Society in publishing illustrations and descriptions of fossils collected in Great Britain has been materially assisted by an allotment of £100, from the Government Publication Grant administered by the Royal Society, towards the issue of the monograph on corallian ammonites. Other donations mentioned in the report include sums of money received from the Colston Research Fund of the University of Bristol and from Miss Mary S. Johnston. Monographs which are also in progress include Pleistocene Mammalia (Prof. S. H. Reynolds), Cretaceous Belemnites (Prof. H. H. Swinnerton), Gault Ammonoidea (Dr. L. F. Spath), Great Oolite Brachiopoda (Dr. Helen Muir-Wood), Dendroid Graptolites (Dr. O. M. B. Bulman) and Palaeozoic Asterozoa (Dr. W. K. Spencer). The following officers were elected for the ensuing year: *President*, Sir A. Smith Woodward; *Treasurer*, W. E. F. Macmillan; *Secretary*, Dr. C. J. Stubblefield.

Mayan Chronology: New Evidence

A JOINT expedition of the Smithsonian Institution, Washington, and the National Geographic Society, which is engaged in the excavation of a site at Tres Zapotes, in the State of Vera Cruz, southern Mexico (according to a communication issued by Science Service, Washington), has discovered a date monument which, it is anticipated, will settle a much-debated question of the authentic age of the reputedly earliest known dated Mayan object, and at the same time determine how and when the ancient Maya first spread over Central America. The site at Tres Zapotes, it is to be noted, is at least one hundred miles west of what had hitherto been believed to be the Mayan zone. Reports of the early results of excavation indicate that the site at Tres Zapotes is early; but the dating of the recently discovered monument is in the so-called 'short' style, which has generally been regarded as a late invention. Apart from its intrinsic interest, the question whether this style of dating was or was not in use in the early period of Mayan civilization is of importance in its bearing on the age of the famous jade statuette of a priest now in the National Museum, Washington.

This statuette bears a dating equivalent, on the Spinden correlation, to May 16, 98 B.C., and if this be taken at its face value, the statuette is the oldest known dated Mayan object. The date, however, is written according to the 'short' system, and question, therefore, has been raised whether the dating is contemporary, or was added in a later period, or whether, indeed, the statuette itself may not be an archaistic piece. Dr. Matthew W. Stirling, who is in charge of the excavation, has summoned a conference of archaeologists to be held on the site, to discuss whether they confirm his conclusion that the newly discovered monument is 'early'.

Eoliths

A COMMUNICATION from Mr. A. S. Barnes traverses the arguments put forward by Mr. J. Reid Moir for the human origin of the pre-Crag implement (see *NATURE* of January 28, p. 151) and deals *seriatim* with the characters upon which he relies. The problem of the differences between natural and human flaking is discussed by Mr. Barnes at length in the current issue of the *American Anthropologist* (41, 1, 1939, p. 99). He there maintains that the arguments for the human origin of pre-Crag implements are for the most part purely subjective, while it has been shown that purely natural forces are able to produce flaking similar to that on eoliths, and further, that the flaking on eoliths differs from that on human work. Although attempts have been made to formulate objective differences between the flake detached by man and those detached by natural agencies, such as 'resolved flakes' and flakes with certain other characteristics, these effects, Mr. Barnes holds, are found on flake fractures by fortuitous pressure as well as by man. After recapitulating the factors operating in natural and artificial fracture, Mr. Barnes goes on to suggest that a criterion of human workmanship, readily measurable and common to both classes of flaking, natural and artificial, is to be found in the angle platform-scar, which he defines as the dihedral scar formed by the intersection of the surface on which the blow has been struck, or pressure applied, and the surface of the scar left by the flake removed. As the result of an investigation of a large number of specimens by this method it has been found that an industry, or supposed industry, may be regarded as of human origin if not more than 25 per cent of the angles platform-scar are obtuse, that is, 90° and over. None of the eoliths examined by Mr. Barnes complies with this criterion, and, he maintains, cannot therefore be considered to be of human origin.

Encouraging Inventions

THE Paris International Trade Fair will be held during May 13-20. An interesting feature is the Inventions Competition (*Concours d'Inventions*), which is open and free to every inventor. An invention of any type may be entered. It may take the form of a new apparatus or device or it may be an improvement which can be incorporated in existing machinery or material. There is a strict

limitation that the invention must not have been exhibited for any other competition. Each competitor must also attach to his entry form a copy of his patent specification, or, if the invention be not patented, a notice setting forth its aims and functions and, when possible, a résumé of its technical qualifications. If possible, actual models (in working order) are to be submitted, but if this cannot be done, permission may be obtained for their presentation by means of a plan. The jury decides whether the plan submitted is sufficiently explicit in itself to convey to experts, and to the public, a clear representation of the functions and operation of the invention. The total area allotted to each exhibit will as a rule not exceed one square metre, but by special application to the committee larger models may be exhibited. All inventions entered for the competition are displayed in a special hall for the duration of the Fair and should be forwarded so as to arrive not later than May 6, addressed Foire de Paris, Concours d'Inventions, Porte de Versailles, Paris 15. The exhibits are classified under many headings, including engineering, medical apparatus, domestic economy, games, travel and camping, office equipment, publicity and education. Competitors whose inventions are not patented may apply for a certificate of guarantee affording protection in France for a period of twelve months from the opening date of the Fair. Entry forms can be obtained at the London Office of the Foire de Paris, 17 Tothill Street, Westminster, S.W.1, and must be completed by March 31.

Combustible Material in Electric Power Stations

EARLY in this century, after a fire at Bristol, rubber-covered cables for switchboard work were rarely used. The recent inquiry on the fire at the Kingston Power Station should accelerate the demand for the use of non-combustible materials alone in main power stations. It was stated in evidence that about 850 gallons of inflammable oil and about 14,000 lb. of solid compound fed the flames. Fires due to oil have been perhaps more numerous in America and Germany than in Great Britain; but recent events show the necessity of getting control of a fire in a power station at the earliest possible moment. The modern oil circuit-breaker (switch) has proved very trustworthy in practice. At its rated capacity it will clear any electric faults with certainty; but in very exceptional circumstances it may fail. The chiefs of supply stations are now paying great attention to the problem of oil-less circuit breakers. Several foreign makers have for the last few years been successfully producing oil-less breakers, particularly the A.E.G. Co. in Berlin, the Brown-Boveri Co. and the Oerlikon Co. in Switzerland. The A.E.G. Co. manufactures a special breaker called a chemical resin breaker for service in unattended substations where the air-blast type could not receive adequate supervision and maintenance. A very profitable and urgent line of inquiry for the industrial research worker would be to try to discover non-combustible liquids and solids of high insulating value for transformers, switches and electric wires. Some

fairly satisfactory liquids and compounds have been found, but their cost at present is far too high for use in bulk. It is all a matter of finance. Textile glass has recently been invented. It seems probable that as a wrapping for electric wires it will have a great future.

Agricultural Research and the Farmer

A BROADSHEET "Bringing Science to the Farm" issued by P.E.P. (Political and Economic Planning) directs attention to defects in the present system of putting the results of agricultural research at the disposal of the farmer. Some of the difficulties are familiar in other attempts at the popularisation of scientific discoveries, notably the superimposition of lecturing on research. Not only does such work impede actual research, but also research ability is by no means invariably linked to lecturing ability, and poor exposition may retard rather than help the spread of agricultural knowledge. The broadsheet urges a thorough overhaul of the provincial advisory service, which is not only seriously understaffed but has lagged behind the rapid diversification and specialization of the sciences concerned. Inadequate arrangements exist for liaison between the provincial advisers and research institutes not situated at their centre, or within their province as well as between the research institute and the farmer. The efficiency of the advisory service moreover depends primarily on the rateable value of the county and is controlled by the county agricultural committees, which cannot be expected to have the same scientific outlook and aims as the research and provincial advisory workers. County organisers do not always refer to the provincial advisers' problems which are beyond their own capacity, and the county organiser is often laden with many other duties besides advisory work. The broadsheet criticizes the annual reports of the research stations from the point of view of propaganda and also the manner of distribution of the official leaflets for farmers issued by the Ministry of Agriculture as well as the meagre use made of films, and lays special stress on the place of the educational services as the fundamental link between research and practice.

Colloquium on Sex Hormones

IN June 1937 a colloquium on sex hormones was held in Paris under the auspices of La Fondation Singer-Polignac. This colloquium was attended by men of science from France, Denmark, the United States, Canada, Great Britain, etc. The meeting lasted ten days, morning and afternoon sessions being held for the reading of papers on most days. The wide international representation of active investigators led to great interest being taken in the papers and to vigorous discussion. The papers presented, together with summaries of the discussions, were afterwards published in one volume for private circulation. They have now been republished in five numbers, each containing five papers, in the series of "Actualités Scientifiques et Industrielles" (Paris: Hermann et Cie). The first number appears under the general title "Les Propriétés des Hormones Sexuelles". The second number deals with "Ovula-

tion, Menstruation, Gestation". The third contains papers dealing with the pituitary. The fourth is entitled "Régulations générales. Influence des facteurs nerveux et externes"; and the fifth number contains papers on a variety of subjects such as pathology, toxicity, antihormones and cancer. The final publication of this material concludes the record of the colloquium, which will be long remembered by those taking part as a particularly happy and profitable occasion upon which La Fondation Singer-Polignac should be most heartily congratulated.

Lake District Roads

THE main object of the Friends of the Lake District is to have the Lake District made a National Park; but they insist on the necessity of guarding against the present tendency to undue development of motor-roads and motor-transport which would ruin the beauty and solitude of the district. The theme is developed at length in a pamphlet entitled "A Road Policy for the Lake District" published by the Friends of the Lake District, Ambleside. The essential Lake District is within a radius of some fifteen miles from the Langdale Pikes: this is the area that needs to be protected. There should be good motor-road access to this area and around it, but there should be no increase in the two or three good routes which go through this area. Moreover, in order to preserve the amenities, which give the Lake District much of its claim to preservation as a park, the width of roads should not be increased and through fast traffic thereby encouraged, dead-end roads which end in a cul-de-sac should not be made available for through traffic, and certain by-roads should be closed entirely to motor-traffic. The pamphlet discusses these matters at length as well as the good and bad examples of road widening that have already been carried out. Above all, it advocates a policy that suits the requirements and amenities of the district rather than a standardized national policy which has little or no relation to local requirements.

Insurance Against Natural Calamities

THIS is a matter which has received a considerable amount of attention from time to time, and here and there premiums against such risk have been accepted, but in general, however, such risks are not taken by companies except for abnormally high premiums, for the simple reason that the place, time and destructive energy of the phenomena cannot be foretold, nor do they occur with any regularity. The problem has been examined by H. Lenz-Stauffer (*Revue pour l'étude des calamités*, 1, No. 3; 1938). The first international conference on this topic, held in Paris on September 18-17, 1937, expressed the hope that research would be made into the problem of the application of the principles of insurance to natural calamities, an application considered until the present time not capable of realization. The author considers the problem from three different angles with regard to the Union Internationale de Secours: (1) with the Union as the insurer against the risk; (2) with the Union as the

insured party against the risk; (3) with the Union encouraging in a general manner insurance against such calamities and contributing to its realization. The article may be commended to those concerned with insurance against damage by earthquakes, tornadoes and the like.

Earthquakes Recorded at Tokyo

WE have received the seismometrical report of the Earthquake Research Institute, Tokyo Imperial University, 1938, parts 1-2 (Jan. 1-June 30, 1938). This includes a first list of twelve stations attached to the Institute together with their latitude and longitude co-ordinates to the nearest second of arc, and their distances in kilometres from Tokyo. Following this is a table of twenty-two earthquakes sensible in Tokyo during the period under consideration. It would be an improvement if the headings to the columns in this table were given in English as well as in Japanese. Next is a map on a square of approximately 3° edge having Tokyo at the centre, showing the distribution of the epicentres. It is notable that these are elongated in a direction north-east-south-west, and otherwise fairly uniformly distributed. Eight are submarine and off the north-east coast of the main island of Japan. Finally there are twelve reproductions of seismograms from the Tokyo (Hongo) station for the shocks of February 7, May 23 and June 6, six being normal and six acceleration seismograph diagrams, all very well reproduced. The publication provides valuable data for seismological studies.

The Smithsonian Institution

THE report of the Secretary of the Smithsonian Institution for the year ended June 30, 1938, refers to the completion in June of two full years of the Smithsonian radio programme in co-operation with the United States Office of Education (Publication 3489. Pp. viii+117. Washington, D.C.: Government Printing Office, 1938). These educational broadcasts have covered the various fields of the Institution's activities—science, invention, history and art—and have been widely popular. An outstanding accession to the National Museum has been a collection of molluscs obtained through the Francis Lee Chamberlain fund, which numbered more than a million specimens. Numerous specimens were brought back for the National Zoological Park by the National Geographic Society-Smithsonian Expedition to the East Indies. The Bureau of American Ethnology dispatched an expedition to South America to make extensive studies of the Indian tribes of the western part of that continent. The Division of Radiation and Organisms has developed an improved method for measuring plant growth substances concerned in the bending of plants towards the light, as well as a new automatic apparatus for measuring and recording photosynthesis continually, and an apparatus for the determination of chlorophyll. The Smithsonian solar observing station on Mount St. Katherine in Egypt was abandoned, and construction of a new station on Burro Mountain, near Tyrone, New

Mexico, was begun. The Astrophysical Observatory has undertaken the re-computation of all solar-constant values from 1923 to the present time.

Academy of Sciences of the U.S.S.R.

At a plenary session of the Academy of Sciences of the U.S.S.R. recently held in Moscow the following officers were elected: *President*, V. L. Komarov; *Vice-Presidents*, O. J. Schmidt, I. M. Gubkin, E. A. Chudakov, A. A. Bogomolets, A. J. Vishinsky, T. D. Lysenko, V. N. Obruchev, A. E. Fersman. The secretaries of the eight newly constituted departments of the Academy, elected at a previous session of the Academy, become *ex-officio* members of the Presidium. They are: Department of Economics and Law, E. S. Varga; Department of Technical Sciences, V. P. Nikitin; Department of History and Philosophy, A. M. Deborin; Department of Geology and Geography, P. I. Stepanov; Department of Biology, L. A. Orbeli; Department of Physico-Mathematical Sciences, A. N. Kolmogorov; Department of Languages and Literature, I. I. Meshchani-nov; Department of Chemistry, A. N. Bakht.

Scholarships in Electrical Engineering

APPLICATIONS, which must be received not later than April 15, are invited for the following scholarships awarded by the Institution of Electrical Engineers: *Duddell Scholarship* (£150 per annum, tenable for three years), open to British subjects less than nineteen years of age on July 1, 1939, who wish to take up a whole-time day course in electrical engineering; *Ferranti Scholarship* (£250 per annum, tenable for two years), open to British subjects less than twenty-six years of age on July 1, 1939, who are students or graduates of the Institution and have been such for not less than two years, who desire to carry out whole-time research or postgraduate work of an electrical engineering nature; *Swan Memorial Scholarship* (£120, for one year), open to British subjects less than twenty-seven years of age on July 1, 1939, who have completed a recognized course in electrical engineering or science of at least three years, and who desire to carry out whole-time research or postgraduate work of an electrical engineering nature; *Silvanus Thompson Scholarship* (£100 per annum and tuition fees, tenable for two years) for works employees who are the sons of parents of limited means, open to British subjects less than twenty-two years of age on July 1, 1939; the successful candidate will be required to make up a whole-time day course in electrical engineering at an approved university or technical college. Further information can be obtained from the Secretary, Institution of Electrical Engineers, Savoy Place, London, W.C.2.

Announcements

PROF. JOSEPH H. HILDEBRAND, professor of chemistry in the University of California, has been awarded the Nichols Medal of the New York Section of the American Chemical Society.

M. BERNARD LYOT, of the Meudon Observatory, has been elected a member of the Section of Astronomy of the Paris Academy of Sciences in succession to the late A. de La Baume Pluvinel.

DR. J. M. STAGG has been appointed superintendent of Kew Observatory, Richmond, in succession to Dr. F. J. W. Whipple, who retired on March 31.

THE Masters Memorial Lectures of the Royal Horticultural Society will be delivered in the Society's New Hall in Greycoat Street, Westminster, on April 18 and 19 at 3.30 p.m. by Dr. J. C. Willis, on "How Plants have found their Homes".

At a meeting of the Microchemical Club on March 11 the following officers were elected: *Hon. Treasurer*, Dr. L. H. N. Cooper; *Hon. Secretary*, Mr. W. F. Stephenson; *Hon. Librarian*, Miss I. Hadfield; *Members of Committee*, Miss M. Corner and Mr. J. R. P. O'Brien.

THE American Social Hygiene Association has awarded the 1939 William Freeman Snow Medal to Dr. Thomas Parran, Surgeon-General, United States Public Health Service, "for his great contribution to the health and happiness of the American People through his persistent efforts against syphilis and the conditions which favour its spread".

AN informal conference on "Internal Strains in Solids" will be held during July 11-13 at the H. H. Wills Physical Laboratory, University of Bristol, under the joint auspices of the Physical Society and the University of Bristol. The Conference is open to all members of universities or research institutions. Further information can be obtained from Prof. N. F. Mott, H. H. Wills Physical Laboratory, The University, Royal Fort, Bristol 8.

THE thirty-seventh annual meeting of the South African Association for the Advancement of Science will be held in East London during July 3-8, under the presidency of Prof. G. H. Stanley. The British Association Medal for 1938 will be awarded to Miss Jean Murray, of the Division of Plant Industry, Pretoria, for her paper entitled "An Investigation of the Inter-relationship of Vegetation, Soils and Termites". A symposium on "The Need for the Investigation and Conservation of Human Resources in South Africa" is being organized by Dr. E. G. Malherbe, director of the National Bureau of Education and Social Research, Pretoria. Further information can be obtained from the assistant general secretary, Mr. H. A. G. Jeffreys, P. O. Box 6894, Johannesburg.

In the ninth report of the Committee for Atomic Weights of the International Union of Chemistry, the only change proposed is the atomic weight of phosphorus, which is now taken as 30.98.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 605.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The Time Involved in the Process of Nuclear Fission

BOHR¹ has discussed the process of nuclear fission in uranium and thorium under neutron bombardment on the assumption that a neutron is first captured by the nucleus and that later the energy of excitation of the compound nucleus is concentrated in motion of some special type which leads to deformation and ultimately to division of the system. From this point of view, it is of interest to try to obtain an estimate of the life-time of the compound nucleus before fission, and Green and Alvarez² have reported upon experiments with a modulated beam of neutrons produced in the Berkeley cyclotron which show that this life-time must be smaller than 3×10^{-12} sec. I have recently obtained evidence of an asymmetry in the spatial distribution of the fission fragments, in the case of uranium bombarded by fast neutrons, from which a limiting time very much smaller than this may be deduced. On the basis of considerations given below, it would in fact appear that the mean life of the intermediate nucleus cannot be longer than about 5×10^{-13} sec. in this case.

In essence, the experiments consisted in collecting the fission products from a 'thick' layer of uranium bombarded by neutrons, in thin sheets of polythene, when different thicknesses of absorbing material were interposed between the uranium and the collector and different orientations were adopted with respect to the stream of neutrons from the lithium target. (Lithium bombarded by deuterons, 100 μ a. at 800 kv., was used as source of fast neutrons in these experiments.) When the active products were collected in the forwards direction with respect to the neutron beam, and aluminium was used as absorbing material, an experiment was first made to see whether the normal 'thick layer absorption curve' was obtained. This was found to be the case; the amount of activity collected on the polythene sheet appeared to vary accurately as the square of the remaining range of the particles, when a small residual effect, ascribed to ²⁴Mg and ²³Na recoiling from the aluminium itself, was allowed for. A single range of 3.80 mgm./cm.² was deduced from these results. An absorption curve for the fission products projected in the backwards direction was then taken and compared with the first. Within the accuracy of the experiment (about 5 per cent) both the range of the particles and the total yield of the active products were the same as in the forwards direction.

A more sensitive test for asymmetry was next applied. A 'sandwich' was made of a thick layer of uranium between gold foils each 6.74 mgm./cm.² thick, and the activities collected on equal polythene sheets, placed in contact with the gold on either side, were compared after the composite system had been irradiated with neutrons. The general activity was reduced to one eighth of that from an uncovered

layer of uranium, and 10 ± 3 per cent more was obtained on the forwards collector than on the other. When a 'sandwich' was made with gold foils 7.13 mgm./cm.² thick, 19 ± 3 per cent more activity was obtained forwards than backwards.

An asymmetry of the type observed shows that, after capture of the neutron, fission of the nucleus usually occurs before the original momentum of the system has been lost. On the existing data concerning the ranges of the heavy radioactive recoil atoms, an estimate of this time may be made. Remembering that the momentum of a 14-million electron volt neutron is roughly the same as that of the least energetic of the α -particles from the natural radio-elements, and that in the present instance the path of the compound nucleus is in solid uranium, a value of 2×10^{-13} sec. is obtained. A time of the same order of magnitude will be required even for the compound nuclei formed by the capture of neutrons of much less energy. Taking all things into consideration, therefore, 5×10^{-13} sec. seems a safe upper limit to the lifetime of these compound nuclei.

Having drawn the main conclusions from the qualitative observation that more activity is collected, through a given thickness of absorber, in the direction of neutron motion than in the reverse direction, it is interesting to try to calculate the magnitude of the asymmetry to be expected on the assumptions which have been made. If a neutron of mass m and energy E is captured into a compound nucleus of mass $2M$, and if this then breaks up with the release of energy $2Q$, in the simplest case, when the break-up is into fragments of equal mass, the relative energy difference, $\Delta Q/Q$, between forwards and backwards fragments, is $2(mE/MQ)$. With $M = 120m$ and $Q = 7E$, $\Delta Q/Q = 0.07$. On any reasonable assumptions, the relative difference in range, $\Delta R/R$, for heavy atoms of the energy in question, will be of the same order of magnitude. This difference, of course, refers to the actual range; when an absorber is used, the relative difference in remaining range is correspondingly greater. With an absorber which reduces the activity collected from a thick layer to only 9 per cent of the total activity without absorber, theoretically a remaining range of 30 per cent of the full range is to be expected. In such a case the relative difference in remaining range between forwards and backwards fragments is about 25 per cent, with the figures quoted, and roughly 60 per cent more activity is to be expected on the 'forwards' collector than on the other. Even taking count of the smaller difference which would be contributed by fission products formed by capture of neutrons of smaller energy, a 30 or 40 per cent asymmetry should result. It is not easy to reduce this figure to the 10-20 per cent which is all that is observed. However, at this stage, the discrepancy is not important.

The experiments which have been described were made possible by the co-operation of members of the Cavendish High Voltage Laboratory, to whom I wish to express my thanks.

Cavendish Laboratory,
Cambridge.

An Effect of Gamma Radiation on Egg Albumin

It has previously been shown that the electrophoretic mobility of particles of inorganic sols and suspensions can be influenced by small doses of X- and gamma-radiation. The mobility does not vary monotonically with the dose but exhibits a series of maxima and minima^{1,2}.

A similar effect has now been observed with egg albumin. The technique employed was that of Freundlich and Abramson³, who have shown that the mobility of quartz particles covered with protein is equal to that of the protein itself. Samples of albumin in dilute acetate buffer solutions were exposed to increasing doses of gamma radiation, the irradiated solutions added to a quartz suspension, and the velocity of the composite particles under the influence of an electric field was determined with the ultra-microscope. Care was taken that sufficient protein was present to coat the quartz completely, and the buffer was maintained at the same strength in the initial and final solutions.

The results of a typical series of experiments are given in the accompanying graph, in which the percentage change of mobility is plotted against the time of exposure. A significant effect can already be observed after an exposure of 30 minutes, and as in the case of the inorganic sols, the curve relating the dose with the change of mobility passes through a minimum and a maximum. The probable error of a single velocity determination was found to be 0.5 per cent. The rate of irradiation as estimated from the amount and disposition of the radium employed was rather less than 3 rontgens per minute. Experiments are in progress to determine it with greater precision.

It is interesting to note that if unirradiated protein is added to a quartz suspension and the solution is then irradiated, the mobility of the composite particles remains unchanged over the range of doses investigated.

A Positive Beam in Cathode Ray Tubes

DURING the course of work on behalf of the Radio Research Board of the Department of Scientific and Industrial Research, certain phenomena have been observed in high vacuum cathode ray tubes of a commercial type.

The electrode system of this type of tube consists of an indirectly heated cathode, surrounded by a cylindrical electrode to control the electron quantity; an accelerating anode; a focusing anode; a final gun anode; and the two pairs of deflecting plates, each being connected separately. The fluorescent screen (blue, with short delay) is at a considerably lower potential than the gun anode, so that when electrons are projected from the gun with velocities corresponding to about eleven hundred volts or less, they slow up completely before reaching the screen, reverse their direction of travel, and finally return towards the gun. Under these latter conditions, when there is no fluorescent spot on the screen due to the electron beam, a faint, slightly more greenish spot has been observed, which can be brought to a comparatively sharp focus by reducing the potential on the electron focusing anode. Furthermore, the brilliance of this spot can be controlled by the electron quantity control electrode in the same manner as the electron beam.

This new spot first appears when the gun potential is about five hundred volts positive, increasing in brilliance up to a gun potential of about eleven hundred volts, above which it becomes unstable. With a further increase of potential the electron beam also reaches the screen, but also in a very unstable condition, wandering over the screen at random. During this condition, the newly observed spot is also present, in close proximity to the electron spot. Finally, when the potential is raised to about twelve hundred and fifty volts, the electron beam becomes stable and the new spot disappears. It is found that the screen has been badly damaged in the region of the spot, and it is thought that this damage may be due to bombardment by heavy particles moving relatively slowly.

Experiments made with electrostatic and magnetic deflecting fields indicate that the new spot observed under the above conditions is caused by a beam of positive ions. It has been further noticed that there is a very considerable external negative electrostatic charge on the glass of the tube in the region of the spot. This charge is sufficient to block the grid of an amplifying valve when a lead from the grid end of its high impedance input circuit is moved into contact with the glass in the region of the spot. Experiments made with an electrometer triode also show that there is a concentration of charge on the inner wall of the cathode ray tube having a positive potential of several hundred volts. It is a significant fact, when the nature of the beam is considered, that the electron beam produces no indication on the electrometer valve.

Considering the phenomena, especially the manner in which brilliance and focus are affected by the electron beam controls, it would appear that the production of positive ions is a secondary effect from the primary electron stream, possibly due to the slowing up of the beam and the slight trace of residual gas in the tube, although the tubes in question are of the hard or high vacuum type.

To sum up, it appears that positive ions can be generated in some types of cathode ray tubes having

high vacua, and that these ions can travel towards the screen, causing bad damage with attendant loss of fluorescence. This effect should be especially noticeable in cathode ray tube systems employing mixed electrostatic and magnetic scanning, where a line will appear across the screen after some use, owing to the fact that the ion beam is not appreciably deflected by the magnetic field.

Thanks are due to the Department of Scientific and Industrial Research and the Medical Research Council for permission to publish this note.

Surface Structures of Possibly Atomic Dimensions using Autoelectronic or 'Field' Emission from Fine Metal Points

WE have set out to study the contamination of metal surfaces, using the field emission from fine points to give large-scale patterns representing the angular distribution of electron emission.

The general technique adopted is similar to that described by Müller^{1,2}, but we have found that with the wide-angle beams obtained a spherical bulb is desirable. The patterns which we have obtained from clean tungsten are so well defined that we feel it may be of general interest to describe the results so far obtained.

A fine tungsten point is mounted on a thick filament in the centre of a spherical bulb, one half of which is coated with fluorescent material. The anode consists of a carbon film on the other half of the bulb.

After suitable exhaust treatment, the filament is dimmed to room temperature or a little above, and a voltage of the order of 10 kv. is applied to the anode. An electron pattern of the emitting point is then obtained on the screen.

In our experiments the points have been different from those of Müller, being formed by electrolytic etching of fine wires of diameter 0.05 mm. The solid angle subtended by the pattern on the screen is considerably wider than Müller shows, and contains more pattern elements.

Fig. 1.
PATTERN FROM CLEAN TUNGSTEN

In Fig. 1(a) is shown a photograph of a typical pattern on the screen. The symmetry of the pattern will be at once apparent, and the dark spaces can be identified, as Müller has done, as corresponding to the directions of the normals to the main lattice planes in the crystal. It is noteworthy that, except when the surface is heavily contaminated, there appears to be no luminosity in these areas.

In the case under consideration, the crystal has a cubic structure, and the centres of the large octagons correspond to the (100) planes. The small well-defined circles forming triangles are the (211) planes, and the centre of the main rectangle corresponds to the (110) plane. The fainter ones either side of the (110) are the (221) planes. The centres of the triangles corresponding to the (111) planes are not fully dark.

From the emission-voltage characteristics, the radius of the point and the size of the emitting area can be approximately estimated, using the Fowler-Nordheim formula^{3,4}. For the point shown in Fig. 1(a) the radius is 1.5×10^{-4} cm., and the emitting area is 2.5×10^{-11} cm.². Optical measurement indicated that the point radius was 5×10^{-4} cm.

In Fig. 1(b), we show the pattern obtained with a somewhat larger point. (A rough measure of the size is given by the voltage necessary to obtain the pattern.) It will be observed that the pattern is basically the same as in Fig. 1(a), but that the dark spaces are surrounded by multiple lines. The bright parts of the pattern are made up of small twinkling spots in rows forming the multiple lines, shown in Fig. 1(b). From the number of spots present, and the emitting area, these spots must correspond with areas of atomic dimensions. Their agitation is quite clearly a function of temperature.

Using thoriated tungsten points, we have found that the basic tungsten pattern can be obtained. The surface can then be covered with a monatomic layer of thorium. The patterns obtained give some idea of the way the surface becomes covered.

It seems to us that the technique described offers an extremely simple method for the study of metallic surfaces and the contamination of such surfaces. For example, the arrival and removal of gas ions can be clearly observed.

We hope to publish our detailed results in the near future.

Magnetic Evidence regarding the State of Manganese in Glasses

MUCH controversy centres around the role of manganese as a colorant of glass. Mellor¹ states that manganese colours alkaline glasses pink to violet under oxidizing conditions. According to Thorpe², the full colour is only developed when manganese is in a fully oxidized condition (Mn^{IV}). In Fuwa's³ opinion, the manganic oxide is responsible for the pink colour, and colourless manganese in glasses is bivalent.

Notable contributions on the subject have been made by Bancroft and Nugent⁴, Solomin⁵, Childs and co-workers⁶, Turner and Weyl⁷, Springer⁸, Hoffman⁹ and others. According to Sir Herbert Jackson¹⁰, none of the evidence is conclusive. An attempt has been made by us to clarify the issues by the aid of

magnetic susceptibility measurements of the manganese glasses. Borax and phosphate glasses have been chosen to start with on account of their availability in the pure state and the simplicity of their preparation.

The melts were made in an electric furnace. The colour conditions could be determined at any time by removing a small bead on a platinum wire. The melt could be made coloured or colourless at will. It was decolorized with tartaric acid and it regained its full colour on prolonged heating in air. Manganese was estimated by the 'bismuthate method'. The magnetic measurements were made on a balance of the Gouy type.

In the case of the decolorized samples, the experimental value of χ was found to be 268.3×10^{-4} . This compares well with the theoretical value 269.3×10^{-4} for divalent manganese, showing that manganese in the decolorized product is in the divalent state.

It was found that in the case of the coloured samples the susceptibility for manganese ion had a value intermediate between those required for divalent and trivalent manganese on the well-known Stoner and Van Vleck formula.

On exposure to ultra-violet light from a quartz mercury vapour lamp with a Wood filter, it was found that the decolorized glass gave an orange-red fluorescence resembling that obtained in the case of the anhydrous manganese halides, thereby lending further support to the view that manganese is divalent in this case¹¹. The coloured sample did not exhibit this type of fluorescence.

Phosphate glass prepared from microcosmic salt was also similarly treated. The coloured product was non-fluorescent while the decolorized sample fluoresced with an orange-red glow, indicating divalency of manganese in the reduced glass. The phosphate glasses are being examined by the magnetic method, and the preliminary results indicate complications arising from the probable polymerization of the manganese salts formed.

It is interesting to recall here that the name pyro-lusite has been derived from $\pi\lambda\phi$, fire, and $\lambda\omega\epsilon$, I wash, owing to the use of this material by the ancients for the removal of colour from glass tinged by iron.

The controversial mechanism of this change is amenable to a satisfactory treatment by the methods described above. Full details of these studies will be communicated shortly in papers to be published jointly with Messrs. Brahm Prakash, B. D. Khosla and Abdul Hamid.

Jahn-Teller Theorem and the Arrangement of Water Molecules around Paramagnetic Ions in Aqueous Solutions

It is well known from X-ray studies that in many of the highly hydrated salts of the iron and the rare earth groups the cation is surrounded by an octahedron of water molecules. This distribution fits well with the observed magnetic properties of these salts; first, it gives an electric field of predominantly cubic symmetry about the central cation, as required by the magnetic data, and secondly, it gives the potential of the electric field the proper sign demanded by the magnetic data. The magnetic data, however, further require (1) that the field, though predominantly cubic in symmetry, should deviate from it considerably, since the cation in these crystals exhibits, in general, a strong magnetic anisotropy, and (2) that for a given cation the magnitude and the asymmetry of the electric field about it should be nearly the same in the different hydrated salts containing the ion, since the magnetic anisotropy of the ion is found to be of the same order of magnitude in all these salts. These requirements will be satisfied in a simple manner if the octahedron, instead of being regular, deviates from it slightly—a small deviation is permitted by the available X-ray data—and the deviation is determined by the nature of the cation in the centre. This arrangement appears very probable in view of the important theoretical result obtained recently by Jahn and Teller¹, namely, that if the electronic state of the central ion is degenerate, the system will be stable only if there is enough asymmetry in the system to remove the degeneracy (except, of course, the special two-fold degeneracy of Kramers). This minimum asymmetry required for stability supplies then the mechanism by which the cation can in a manner determine the geometry of distribution of the water molecules around it.

Such an asymmetric arrangement of the water molecules about the cation seems to persist even in the aqueous solutions of these salts. Freed and his collaborators² have found in the observed multiplicity of the absorption lines of the rare earth ions in aqueous solutions evidence for asymmetric electric fields, nearly the same as in the corresponding hydrated crystals. A comparison of the magnetic behaviour of some of the paramagnetic ions, both of the rare earth and the iron groups, in aqueous solutions, with the ideal free-ion behaviour on one side, and with the behaviour of the ions in the hydrated crystals on the other, also leads to the same conclusion.

The large magnetic double-refraction exhibited by aqueous solutions of these salts³ follows as a natural result. Owing to the asymmetry in the distribution of the water molecules about the paramagnetic ion, and the consequent asymmetry of the electric field about the ion, the group as a whole will be magnetically anisotropic, and will tend to orient in the magnetic field. Since the group will also be optically anisotropic, the solution will exhibit double-refraction. Now these anisotropies, according to the views presented here, should depend indirectly on the incipient degeneracy of the electronic state of the central paramagnetic ion, and in particular on the orbital degeneracy. The observation by Chinchalkar⁴ that the double refraction depends on the orbital angular momentum of the paramagnetic ion, and that in particular the double refraction is almost

nothing when the ion is in the S -state, (for example, Gd^{+++}) is significant. Indeed, from the known magnetic anisotropy of the group in the crystal state, and its birefringence, a rough estimate can be made of the magnetic double refraction of the solution, and it is found to be of the right order of magnitude.

A Comprehensive Fundamental Electrical Formula

DR. C. V. DRYSDALE has pointed out that his formula¹ can be applied to the calculation of what are usually called 'electromagnetic forces'; and it then becomes an expression (in vector notation) for the generally accepted principle called the Biot-Savart law. But the experiments to which I referred in *NATURE* of August 7, 1937, have shown that the Biot-Savart law sometimes indicates only a small fraction of the actual force, and have therefore shown the serious incorrectness of the more general formula proposed by Dr. Drysdale.

The accuracy of my experimental results was verified by finding that they were all in close agreement with the formula given in Maxwell's Art. 583. When applied to the case shown in Fig. 2 of my above-mentioned communication to *NATURE*, this formula becomes

$$F = \frac{1}{2} i^2 dL/dy,$$

where F is the force that acts in the vertically downward direction on $MBON$, while this part of the circuit moves through the distance dy in that direction, which movement increases the inductance by the amount dL . The value of dL/dy can be found by differentiating the well-known expression for the inductance of a rectangular circuit. Maxwell's formula says that the vertical force exerted on $MBON$ by $MADN$ and on $MADN$ by $MBON$, is $8.74 i^2$, whereas Drysdale's formula says that the force exerted on $MBON$ by $MADN$ is $0.43 i^2$, and that the force exerted on $MADN$ by $MBON$ is $0.17 i^2$, this last being less than one-fiftieth of the actual force. Here it will be seen that Drysdale's formula contradicts, to a very serious extent, both Maxwell's formula and Newton's laws of motion.

W. F. DUNTON.

46 Grosvenor Road,
Birmingham, 20.
Jan. 30.

¹ *NATURE*, 140, 945 (1938).

MR. DUNTON's measurements do not in any way affect the validity either of my equation, the Biot-Savart law, Faraday's law of electromagnetic induction, or the magnetic flux-cutting equation. His error lies in assuming that it is only the magnetic field of the lower fixed portion M_1ADM_2 of the accompanying circuit which produces a force on the conductor BC ; whereas the only part of the magnetic field produced by the whole circuit which does not

produce a force on BC is that due to BC itself. If for simplicity we consider a very long narrow rectangular loop of breadth b and conductor radius a , the magnetic

force at any distance x from AB and remote from BC or AD is $H = 2I/x + 2I/(b-x)$, and hence if the length of the loop is increased by the amount dy

$$\frac{\partial L}{\partial y} = 2 \int_0^b \{1/x + 1/(b-x)\} dx,$$

neglecting the internal magnetic field in the conductors. But the magnetic force at a corresponding point on BC is $H' = H/2$, and the force on BC or on AD is therefore

$$f = I \int_0^b H' dx = I^2 \int_0^b \{1/x + 1/(b-x)\} dx = \frac{1}{2} I^2 \frac{\partial L}{\partial y},$$

which is Maxwell's formula, with which Mr. Dunton's measurements agreed. He ought actually to have observed a somewhat greater force due to the pressure on the ends of the conductors caused by the constricting effect of the current in the mercury (the 'pinch phenomenon' of Carl Hering), which is covered by the same argument; but the above is sufficient to show that his supposed discrepancy has no foundation.

C. V. DRYSDALE.

Frequency Interpretations in Probability

If he were consistent, de Moivre would not have accepted $5/12$ as the probability in Dr. Jeffrey's problem. (Two boxes, one containing 1 white and 2 black balls, the other 1 white and 1 black. Choose a box; then draw a ball; what is the probability of drawing white? *NATURE*, Feb. 11.) For, according to his definition, the statement that the probability is $5/12$ must mean that there are $12n$ different possible cases, of which $5n$ are favourable, n being an integer. That simply is not true.

The 'modern' who affirms $5/12$ must hold that probability means something other than the ratio of favourable to possible cases. When the cases are sums of 'equally possible' elements, then the probability happens to be that ratio, but not otherwise. De Moivre's definition, or Laplace's modification of it, is not wrong; it is merely unduly limited; it tells us nothing about probability except in a limited class of problems.

The question is then what is the general meaning of probability, and why, in this limited class, does it happen to be measured by the ratio? The question can be answered in accordance either with Dr. Deming's view or Dr. Jeffrey's. My object is not to answer the question, but to point out that an answer is required.

Use of the Termination *-tron* in Physics

IN the invention of names in physics, there appear to be two schools of philological thought as to the meaning of the termination *-tron*. According to one school, it is derived from a Greek word signifying an instrument, as illustrated by *cyclotron* or *thyatron*, whereas according to the other it signifies an elementary particle, as in *positron* and now *mesotron*. The decision as to which is the better meaning is in no way helped by reference to authority, for the ancients appear to have been wholly ignorant of the use of the word in either sense, or indeed in any sense at all. It is perhaps none the worse for that, but it does seem an unnecessary confusion to introduce, out of all possible combinations of letters, exactly the same four to represent a new machine or a new particle. If the termination is to be accepted for both, it is indeed rather hard to think of anything in modern physics to which it might not be applied.

Discoverers are of course free to name their inventions as they please, but there would be, to say the least, a convenience if the chosen name terminated with something expressing the category to which its possessor belongs, so that *-tron* should be restricted to signify either an instrument or a particle, but not both. The names *thyatron* and *cyclotron* have already got into wide use, so that it would seem almost impossible to change them without confusion. On the other hand, *positron* and *mesotron* are household words in the mouths of comparatively few, and to rename them would not cause such widespread trouble. The situation is unavoidably complicated of course by the *electron* and *neutron*, but the division of these as *elec-tron* and *neu-tron* is one which the most illiterate would scarcely make, and *-on* taken by itself—why not for example *poson* and *negon*?—seems the most natural ending for a particle.

Growth-controlling Hormonal Substances of the Hypophysis

STUDYING the substances which accelerate or inhibit the growth of plants, and which are present in different extracts of particular organs of animal body, we have found that the acetonic extract of the anterior lobe of the hypophysis accelerates the growth of plants, while the same extract of the posterior lobe of the hypophysis inhibits their growth.

Later, we experimented with various extracts of organs influencing the growth of animals. These experiments were performed upon young animals of the same breed (rabbits, guinea pigs), and especially upon young rats of about 30 gm. in weight. We

have found in the acetonic extract of the anterior lobe of hypophysis a substance which accelerates the growth of normal young animals compared with controls under the same conditions. This substance is not identical with the somatotrophic hormone of Evans because its physical and chemical properties (freedom from albumin, resistance to boiling, reduced sensibility to alkali, etc.) are different. Compared with the controls of the same breed, the normal size of the animals under treatment is attained under the influence of the substance in a shorter time. The action was evident after two or three injections of the extract.

The acetonic extract of the posterior lobe of hypophysis was found to have an opposite result. After two or three subcutaneous injections of the extract, the growth of the animals became so much inhibited that two or three months later the weight of the treated animals was only slightly increased compared with controls. The treated animals presented quite a normal appearance not only in their behaviour but also in their appetite. The anatomical examination of the animals which were killed has shown no pathological changes in the organs, which were of an inferior average weight compared with the organs of the controls.

There exist, therefore, in the hypophysis not only the somatotrophic growth hormone discovered by Evans, but also other growth-controlling substances, namely, in the anterior lobe a growth-stimulating, and in the posterior lobe a growth-inhibiting substance. We suggest that the substance inhibiting the growth of animals and of plants in the posterior lobe of the hypophysis be named 'amioins'.

Pentose Nucleotides in the Cytoplasm of Growing Tissues

INTEREST in the nucleic acid metabolism of mitosis has in general tended to centre on the nucleus. More recently evidence has been obtained showing an interplay between the nucleic acid metabolism of the nucleus and that of the cytoplasm¹. Studying the ultra-violet absorption spectra of the cytoplasm of growing tissues, we have found them all to exhibit the maximum around 2600 Å., characteristic of the cyclic nitrogenous bases present in the nucleic acids. In contrast, the homologous mature tissues exhibit a different absorption similar to that of the proteins.

The cells from rapidly growing yeast cultures have already² been shown to differ from the cells of the senescent cultures in containing a much higher concentration of the substances absorbing maximally at 2600 Å. An estimate of the total absorbing substances, calculated as yeast nucleic acid, agrees well in order of magnitude with Baumann's data³ for the yield on the extraction of yeast nucleic acid from yeast.

In the tissues of the plant embryo, prepared as they are for rapid growth and division, it has long been known that yeast nucleic acid was present^{4,5}. The absorption spectrum of cells from the rye embryo shows a maximum at 2600 Å., with an additional absorption indicating a high concentration of proteins. Here Behrens⁶ has shown that yeast nucleic acid can be extracted from the cytoplasm of the cell itself.

In the eggs and embryos of animals, pentose nucleic acids have already been demonstrated for the sea urchin¹, chick² and fish³. The absorption spectrum of the *Drosophila* egg cytoplasm agrees well with that of a nucleic acid¹. Moreover, the imaginal disks of the *Drosophila* larva, which are dividing rapidly while the larval cells merely increase in size, have a strongly absorbing cytoplasm the absorption spectrum of which has a maximum at 2600 Å. In the mid-gut of the larva, where the imaginal cells are present in small nests among the larval cells, it is easy to compare the absorption spectra of the two types (Fig. 1). The functional gut cell of the larva has a much lower concentration of absorbing materials, and the shape of the absorption curve is more like that of proteins.

The system of apical growth in the root of plants is another case in point. We have studied the *Allium* root-tip, finding in the zone where mitoses are occurring, cells with a high concentration of absorbing materials the absorption spectrum of which is of the nucleic acid type. Towards the base the cells which will no longer divide have the absorption spectrum of a protein with cyclic amino acids (Fig. 2).

The absorbing substances are probably pentose nucleotides. In the cases of yeast and the rye embryo, yeast nucleic acid has been extracted. In the *Drosophila* and the *Allium* material a strong orcin reaction for pentoses has been obtained in the same tissues, which on micro-incineration show a plentiful residue of ashes that give a positive test for phosphorus. That the pentose, phosphorus and ultra-violet absorbing substances mentioned above occur in the same tissues gives support for the assumption of the presence of nucleotides.

It seems likely that a high concentration of nucleic acids is the basis of the generally noted basophilia of embryonic tissues. Those here discussed are strongly basophilic, in correlation with the high ultra-violet

Fig. 1.

The Enzyme System Transferring the Amino-Group of Aspartic Acid

I HAVE, in recent communications^{1,2}, described a method for the preparation of a purified enzyme from muscle tissue, catalysing the reversible transfer of amino nitrogen from glutamic acid to monocarboxylic α -ketoacids³. The enzyme preparation is inactive with regard to the *Umaminierung*, or 'trans-amination' of aspartic acid, whereas this process is readily effected

by the original muscle pulp⁴. I have since been successful in obtaining from muscle tissue, by means of a modified purification scheme to be described in detail elsewhere, enzyme preparations catalysing the transamination of aspartic acid at a considerable rate in the presence of a thermostable activator, or coenzyme, contained in tissue extracts.

This enzyme preparation still contains the enzyme of glutamic acid trans-amination, but from vegetable materials preparations can be obtained that are active only with regard to aspartic acid while completely indifferent to glutamic acid. The aspartic enzyme differs from the glutamic enzyme in that it is more readily extracted from tissues by aqueous solvents, and also in its higher lability. The glutamic enzyme appears to contain an active group similar to the coenzyme of aspartic enzyme, but less readily dissociable. The chemical nature of the active thermostable constituent is under investigation in this laboratory.

Purification of Uricase

URICASE is an enzyme which catalyses the oxidation of uric acid. It was reported recently by Davidson¹ that he had been able to obtain a preparation of uricase about a thousand times more active than the acetone powder of liver which was used as a starting material. Several purified preparations showed, according to him, a high and fairly constant iron content ranging from 0.15 to 0.20 per cent, which he regards as evidence in favour of the view that iron is a constituent of uricase.

Using a modified method of purification, I have been able to obtain preparations 1,000-1,400 times more active than the acetone powder of pig's liver used as initial material. My preparations are completely colourless, insoluble in water and only sparingly soluble in alkaline buffer solutions. The iron content of these preparations as determined on samples up to 16 mgm. of dry weight, is only 0.02 per cent.

Their catalytic activity is poisoned reversibly by potassium cyanide but not by hydrogen sulphide, α -dipyridyl, pyrophosphate or diethyldithiocarbamate.

The lack of proportionality between iron content and activity in preparations obtained with different methods and the very low iron content (0.02 per cent) in highly purified enzyme preparations make it very improbable that iron is a constituent of uricase.

An account of the purification and properties of the purified enzyme will be given elsewhere.

Marrubiin, a Diterpenoid Lactone

ACCORDING to Gordin¹, marrubiin, the optically active bitter principle of *Marrubium vulgare*, is a lactone, $C_{21}H_{32}O_4$, m.p. 154.5°-155.5°, which on hydrolysis yields marrubic acid, $C_{21}H_{32}O_5$, m.p. 173°-174°, forming an ethyl ester, m.p. 87°.

In the course of an investigation on the constitution of this compound, which has m.p. 158°, we have found that the analytical results and molecular weight determinations given by marrubiin and a number of its derivatives are in agreement with the formula $C_{21}H_{32}O_4$ for the lactone which on hydrolysis gives rise to a monobasic acid $C_{21}H_{32}O_5$, m.p. 197° (methyl ester, m.p. 85°; ethyl ester, m.p. 88°). Hydrogenation of marrubiin and marrubic acid gave the corresponding tetrahydro-derivatives, m.p. 132° and m.p. 187° (ethyl ester, m.p. 95°) respectively, which like the parent compounds are interconvertible.

Determination of active hydrogen indicates that marrubiin contains one hydroxyl group and, since the compound does not appear to form acyl derivatives under the usual conditions, this is in all probability a tertiary alcoholic group; the fourth oxygen atom is present in an oxide system. Marrubiin, which is readily resinified by warm mineral acids and by hot formic acid, gives rise on oxidation with potassium permanganate to a neutral compound, m.p. 211°, and a lactone, m.p. 161° (acid, m.p. 208°), which is also formed along with a liquid acid by the action of ozone, whilst dehydrogenation with selenium furnishes a comparatively good yield of 1:2:5-trimethylnaphthalene (agathaline). It is concluded that marrubiin is a hydroxyditerpene lactone of the manoyl oxide type.

Effect on Bacteria of Continued Cultivation in Lecithin Broth

THE pathogenic properties of bacteria (typhi, dysenteriae, coli) are slowly reduced by daily subcultures (about a hundred) on bouillon containing between 0.2 per cent and 4 per cent colloidal lecithin¹. For the sake of brevity these will be designated as *L*-bacteria and normal organisms as *N*-bacteria.

Particularly interesting results were obtained with *B. typhi murium*, which after four hundred subcultures required 10,000 times the original dosage to produce a fatal effect when injected intraperitoneally into mice (1,000 and 10,000,000 living bacteria, respectively). Neither fifty subsequent subcultures on ordinary media nor twelve animal passages induced a return of the pathogenic properties. The agglutinability of the *L*-bacteria with immune serum produced by the corresponding *N*-bacteria was not measurably lessened, nor was their ability to produce H and O agglutinins in affected animals.

The duration and intensity of the immunity resulting from intraperitoneal administration of *L*-strains were equal to the results observed in surviving animals infected with *N*-strains, and the results were better than those obtained by the injection of 10-100 times as many *N*-bacteria killed at 60° C.

Groups of pregnant mice which received ten oral doses (0.5 c.c. daily) of a 24-hour living broth culture of an *L*-strain of *B. typhi murium* gave birth as normally as untreated controls. A similar group of mice treated at the same time with equal numbers of *N*-bacteria showed 100 per cent mortality.

Three months later, the mice which had been fed *L*-strains were given orally large numbers of *N*-bacteria; the resulting mortality was 15 per cent, whereas controls which had been immunized at the same time with large numbers of heat-killed *N*-bacteria showed a mortality of 80 per cent.

A certain degree of attenuation in virulence was also noticed after passage of *N*-bacteria on ordinary media. After four hundred passages of *B. typhi murium*, the lethal dose was fifty times that of the initial culture. However, in most such cases a few animal passages sufficed to bring the pathogenicity of the strain back to its original degree.

In animals inoculated with *L*-strains the bacteria disappeared from the blood stream and organs within a few weeks and sometimes within as short a time as 48 hours. Animals which had recovered from sub-lethal doses of *N*-strains generally remained carriers for many months.

All the *L*-strains also showed a diminished production of endotoxins. This effect is irreversible in the case of *B. typhi murium*, even after fifty passages on ordinary media; other members of the typhi-coli-dysenteriae group, however, recovered their endotoxicity.

Points from Foregoing Letters

FROM an observed asymmetry in the spatial distribution of the explosion fragments from uranium bombarded by fast neutrons, N. Feather concludes that less than 5×10^{-12} sec. must elapse between the capture of a neutron by the nucleus and the break-up of the system into two heavy fragments. Previously, more direct methods of investigation had indicated that this time must be less than 0.003 sec.

J. A. Crowther and H. Liebmann show that the electrophoretic mobility of egg albumin alternately decreases and increases when exposed to increasing doses of gamma-radiation.

The occurrence in certain circumstances of a beam of positive ions in high vacuum cathode ray tubes of a commercial type is described by J. Forman. It appears to be a secondary effect due to residual gas and causes damage to the fluorescent screen.

Patterns of the emission from fine metal points under autolectronic conditions can be identified, according to M. Benjamin and R. O. Jenkins, as corresponding to the main planes in the crystal lattice. The patterns obtained are made up of twinkling spots which are of possibly atomic dimensions. The technique described lends itself to the study of surface structure and surface contamination.

S. S. Bhatnagar finds that in borax glasses of manganese, the manganese ions in the decolorized variety have an experimental value of magnetic susceptibility equal to 268.3×10^{-6} , which compares well with the theoretical value of 269.3×10^{-6} for divalent manganese. The coloured variety shows a value intermediate between the divalent and trivalent manganese.

On the basis of magnetic and other evidence, K. S. Krishnan concludes that the octahedra of water molecules surrounding the cation in many of the salts of the iron and the rare earth groups, are asymmetric, the degree of asymmetry being determined by the electronic state of the cation in the centre; this arrangement persists in water solutions.

W. F. Duntun argues that the "comprehensive fundamental electrical formula" proposed by C. V. Drysdale, when applied to the calculation of electro-

magnetic forces, will sometimes give results that are inconsistent with Newton's laws of motion, and are very different from the results given by Maxwell's energy method of calculation. In reply, Drysdale points out that the force on a straight conductor depends upon the magnetic field induced by the whole of the remainder of the circuit, and that the proper application of the flux-cutting principle or of the Biot-Savart law gives the same value for the force as that given by the Maxwellian formula.

B. Lustig and H. K. Wachtel state that they have extracted with acetone a growth-stimulating hormone from the anterior lobe of the hypophysis and a growth-inhibiting hormone from the posterior lobe.

Measuring the ultra-violet absorption spectra of the cytoplasm in cells of the rye embryo, the *Allium* root-tip and the *Drosophila* imaginal disks, T. Caspersen and J. Schultz find the absorption band characteristic of the cyclic nitrogenous bases in the nucleic acids. These ultra-violet absorbing substances are present as pentose nucleotides in high concentrations in rapidly dividing tissues.

The enzyme effecting the reversible transfer of amino nitrogen from aspartic acid to different α -ketoacids has been prepared from animal and vegetable tissues by M. G. Kritsmann. The enzyme is associated with a thermostable co-enzyme.

C. G. Holmberg states that the very low iron content (0.02 per cent) in highly purified preparations of uricase makes it improbable that iron is a constituent of this enzyme.

Marrubium, which is the bitter principle of *Marrubium vulgare*, is an unsaturated lactone of the diterpene series, according to A. Robertson and his co-workers, having the empirical formula $C_{18}H_{22}O_4$ and containing a tertiary hydroxyl group and an oxide linking. A number of derivatives have been obtained, including agathaline, which is formed by dehydrogenation with selenium.

B. S. Levin and L. Olitski find that bacteria of the typhi-coli-dysenteriae group, which had been subjected to daily passages in lecithin bouillon, showed a markedly lower pathogenicity than controls grown in ordinary bouillon.

Research Items

Mangarevan Ethnology

THE RANGI HIBOA (Dr. Peter H. Buck) has recently reported on the results of his ethnological observations on the Mangarevan expedition organized by the Museum in 1934, when he spent seventy days on Mangareva (*Bull.* 157, Bernice P. Bishop Museum, Honolulu). The Mangareva (Gambier) Islands lie in latitude $20^{\circ} 20' S.$ and longitude $134^{\circ} 45' W.$, 900 miles from Tahiti, and 1,450 miles from Easter Island, the eastern extremity of Polynesia. The group consists of four islands, which are the unsubmerged peaks of extinct volcanoes, without permanent streams and with only a few springs. The population is much mixed, and only a few families of full-blooded Mangarevans remain. It is probable that at no time did the population exceed more than a few thousand. It was kept within food-producing capacity by emigrations resulting from inter-group struggles for cultivable land and cannibalism. Their speech is a dialect of Polynesian, resembling that of Cook Islands, Tuamotu, and New Zealand. The culture of Mangareva is fundamentally based on the early culture that prevailed in the Society Islands before dispersion took place to Hawaii in the north and New Zealand in the south. The earliest settlers evidently drifted in from the Tuamotus in small groups, bringing no cultivable food plants, and in insufficient numbers to establish an organized system of social classes. They were a simple fisher folk. Later immigrations about A.D. 1300, in the form of organized expeditions, brought food plants from some volcanic group such as the Marquesas, or the Society Islands. They introduced the worship of Tu, the mare, and a highly organized social system. The major gods of the Society Islands are present, and the form of worship and temple follow those of Central Polynesia. The pattern of social organization is orthodox Polynesian, while the material culture has an early Polynesian pattern. Mangarevan culture was thus an offshoot of Central Polynesian culture, which reached the islands by way of the Marquesas.

Propagation of Vaccinia in Chick Embryos

METHODS of cultivating viruses on the embryonic membranes of the developing chick within its egg-shell, which have been devised during the last few years, have been applied to the cultivation of the vaccinia virus, and Lieut.-Colonel W. D. H. Stevenson and Dr. G. G. Butler have recently reported upon their extensive studies of this subject (*Ministry of Health: Repts. on Pub. Health and Med. Subjects*, No. 87. London: H.M. Stationery Office. 4s. net). Glycerinated calf lymph, which is usually employed for vaccination, is prepared by inoculating the skin of calves, collecting the vaccinal material and mixing it, after grinding, with glycerin, water and a small amount of preservative. However carefully prepared, the material contains numbers of extraneous micro-organisms, which are reduced by treatment and storage to a number considered safe. The vaccinia grows well in the egg, and the material so obtained can be used for vaccination. Fertile hens' eggs are used; these are inoculated by a special technique, the eggs are opened on the fourth day of incubation, and the material is

then collected. By adopting certain precautions, it is possible to obtain a lymph free from the extraneous micro-organisms which are so troublesome in ordinary calf lymph. It is suggested that in the future chick membrane lymph may replace calf lymph. Full details of the technique are given in this report, which also contains a critical discussion of the whole subject.

Acetylcholine Formation in Tissues

B. B. DICKSHIT (*Quart. J. Exp. Physiol.*, 28, 243; 1938) studied the formation of acetylcholine in the different tissues of dogs by suspending the tissues in warm eserinized Locke's solution and oxygenating for five hours. The brain cortex, basal ganglia, spinal cord, sympathetic ganglia, auricle, urinary bladder, gastro-intestinal tract and pancreas were found to possess the property of forming acetylcholine. Although all parts of the gastro-intestinal tract could form acetylcholine, the largest quantities were formed by the small intestine in which the nerve plexuses are chiefly responsible. The writers suggest that acetylcholine formation is a specialized function of the nerve cells.

Birds of Nanking

IN the difficulties which beset China at present it is surprising and gratifying to find that publication of scientific papers seems to continue without break. An account of the passerine birds of Nanking and its vicinity has appeared as one of the contributions from the Biological Laboratory of the Science Society of China (*Zool. Series*, 12, No. 9, Shanghai, 1938). It is a guide to a passerine avifauna of 112 species and subspecies, amongst which the finches (with 22 forms) predominate, and the wrens, goldcrests and orioles are each represented by only one species. Analytical keys to the characters of families, species and subspecies, as well as many illustrations of distinctive head-markings, aid in identification. The author, L. T. Chong, has compiled the list from collections which have been accumulating in the museum of the Biological Laboratory since 1925, so that it is possible that additions may still have to be made; but to a Western reader it is remarkable that where so many Western species of birds are represented, there should be such a dearth of subspecies familiar in Great Britain.

Tomato 'Rogues'

GROWERS of tomatoes are often troubled by the appearance of abnormal plants or 'rogues', which are of dwarf habit, have extensive lateral shoot development, with unusual leaf shape, and give low yield. M. B. Crane, of the John Innes Horticultural Institute, has investigated the genetics of these aberrant tomatoes (*Gard. Chron.*, Feb. 11 and 18, 1939). Grafting experiments have shown that the rogue condition is not pathological, and it is probable that unstable genes, which could either determine normal, or mutate to form rogues, are present in the plants concerned. Rogue plants frequently develop normal growth, and it has been found that seeds harvested from trusses at various heights on such a plant, yield varying proportions of rogues. The more general question as to any effect of position of the truss

upon normal genes has been investigated by experiments on a cross between the varieties Kondine Red and Blaby. No differing proportions of characters in the offspring could, however, be associated with varying positions of the trusses in these normal conditions. The control of rogues would appear to be easy, if sufficient care be taken to eliminate abnormal plants during the first potting, and to save seed only from tomato plants which are fully normal.

Mosaic Disease of Cassava

A VIRUS disease which causes a mosaic-like mottling of the leaves of cassava (*Manihot utilisima*) has been known in East Africa since 1894, and there has been an increasing recognition of the serious nature of the disease. H. H. Storey and R. F. W. Nichols, of the East African Agricultural Research Station, Amani, have recently made detailed studies of the malady and its transmission (*Ann. App. Biol.*, 24, No. 4, 790-806; Nov. 1938). Symptoms exhibit wide variation, owing to varietal reactions of the host, and also to differences in strains of the virus. Two groups of strains have been recorded, one giving mild, and the other severe, symptoms. Cassava mosaic has not been transmitted to a healthy plant by mechanical means; but it can pass across a graft union, and has an insect vector, a species of *Bemisia*. The latter can only inoculate a plant through an immature leaf, a fact which should be useful in experiments upon movement of the virus. It has been found already that the virus does not pass out of the inoculated leaf until after eight days. It then moves quickly to the base of the stem, and slowly into the side branches. The presence of a mild strain of the virus does not confer any resistance against the more severe kind.

The Centromere

C. D. DARLINGTON (*J. Genetics*, 37, 341; 1939) finds in *Fritillaria kamschatkensis* that chromosomes lag on the first metaphase plate of meiosis due to failure of bivalent formation, and more frequently as the result of bivalents being crowded off the plate. In about 1,000 first anaphases, 109 lagging chromosomes were found. Of these laggards, 107 showed transverse divisions of the centromere. It is suggested that chromosomes with terminal attachments, chromosomes with similar ends as in the extra chromosome of secondary trisomics and attached X-chromosomes of *Drosophila* may result from this type of division of the centromere. The structure of the centromere is discussed.

Effect of Colchicine on Allium

A. LEVAN (*Hereditas*, 24, 471; 1938: 25, 9; 1939) has studied cytologically the effect of colchicine on mitosis and meiosis in *Allium*. In both types of cell-division the spindle apparatus is more or less put out of action. In mitosis the normal division at the attachment constrictions is considerably delayed. Consequently the two daughter chromosomes are held together, to be included in one nucleus. In meiosis, a similar delay of division occurs, chiasma formation and contraction are reduced, leading to an increased number of chromosomes in the daughter nuclei. In two further papers, by Levan (*Hereditas*, 25, 109; 1939), and J. Rasmussen and A. Levan (*Hereditas*, 25, 97; 1939), the practical aspects of colchicine treatment are pointed out. The proportion of tetraploid shoots from a treated diploid plant depends on the comparative viability of

diploid and tetraploid cells. Tetraploid shoots are much commoner in *Petunia* than in sugar beet for this reason.

Paper from Australian Timbers

A SHORT time ago, an arrangement was made by which the Division of Forest Products in Australia commenced to work in co-operation with the paper industry. The Division of Forest Products is under the Council for Scientific and Industrial Research, and the latter has just issued Pamphlet No. 86 under the title "A Study of the Pulping Properties of three Trees of *Eucalyptus sieberiana*, using the Sulphate Process". This species was selected because of its potential importance at the time the work was planned. The report was prepared by J. C. Cavanagh, H. E. Dadswell, A. W. Mackney, and Miss T. M. Reynolds, and acknowledgments are made to Australian Paper Manufacturers, Ltd., for their financial assistance during the period when the work was being done and prior to the association of other companies with the Division. Thanks are, it is said, also due to the company for the active assistance of its officers in carrying out the evaluations, etc., and also in discussing the problems as they arose. Three trees of *E. sieberiana* (silver-top ash), which is found in favourable quantity and size in the southern coastal districts of New South Wales, were investigated. The object of the work was to study the variability in the yield and the quality of the pulp that could be expected from different parts of one tree and from different trees. Samples of the 'truewood' and the 'heart' of the butt, centre, and top sections of the merchantable bole were accordingly tested. In general, it was found that satisfactory pulps could be obtained from all these samples. The investigation is said to have yielded valuable data, considering the small number of trees handled.

Densities of D₂O—H₂O Mixtures

LONGSWORTH, in 1937, found that at 25° mixtures of D₂O and H₂O are ideal from the point of view of volume changes on mixing. Since the publication of his paper, the density of pure heavy water has been found by Tronstad and Brun to be $d_{25}^{25} = 1.10750$ instead of 1.10790 found by Selwood, Taylor, Hipple and Bleakney and used by Longworth. More recently, Tronstad has given the value 1.10764. This necessitates a recalculation of Longworth's data. E. Swift (*J. Amer. Chem. Soc.*, 61, 198; 1939) has made experiments on the densities of mixtures of heavy water and ordinary water at 5° and 25°, and finds that from the point of view of density these mixtures form ideal solutions at both temperatures. The constants used in Longworth's equation were found to reproduce the results, the only change being that for the specific gravity of pure deuterium oxide. If ΔS is the density difference referred to pure protium oxide (taken as 15 p.p.m. lighter than tap water) then the mol fraction (N) of D₂O in a mixture at 25° is given by the equation $N = 9.257 \Delta S / (1 - 0.033 \Delta S)$.

Non-Stoichiometric Oxides of Chromium

IN addition to the well-known oxides CrO₃ and Cr₂O₃, a large number of oxides of chromium have been reported, including a dioxide CrO₂. A Cameron, E. H. Harbard and A. King (*J. Chem. Soc.*, 55; 1939) have now shown that CrO₂ decomposes thermally in two stages with the formation of two non-stoichiometric oxide ranges: (a) CrO_{1.4}—CrO_{1.1},

and (b) $\text{CrO}_{1.7}\text{--CrO}_{1.8}$. Many oxides previously reported lie in one or other of these ranges. The methods claimed to give the dioxide were examined and it was shown that (i) the product of low temperature decomposition of ammonium dichromate contains nitrogen; (ii) the oxide formed by heating CrO_3 in oxygen is in the non-stoichiometric range (a); (iii) the oxide formed by the action of CrO_3 on chromic hydroxide lies in range (b). The recent work of Moles and González which claimed to have substantiated the individuality of chromium dioxide is thus, apparently, invalid.

Recording Sound by means of Films

SOUND-FILM recording is now a large and important industry. Even in the earliest days of cinematography attempts were made to develop sound-recording on metal and photographic films, but it was not until practical forms of thermionic amplifiers were developed that recording became of more than scientific interest. On February 20 Mr. D. W. Boston read to the London Students' Section of the Institution of Electrical Engineers a paper on the art of sound-film recording. To record sound on film the main requirements are a lightproof box provided with means for driving the film at constant speed and some means of producing a beam of light, so that it falls on the face of the film, and which can be modulated at audio-frequency. As the film runs past the beam of light it produces a trace which when developed appears as a band the width and darkness of which varies according to the method of light modulation employed. This trace is known as the 'sound-track' and depends on the shape of the oscillogram of the recorded sound wave. The lightproof box and associated apparatus is called a 'sound camera'. For reproduction the film speed must be the same as when recording. A beam of light similar to that used in recording, but unmodulated, falls on the sound track and the light passing through the film is modulated by the recorded wave form. The light now falls on photo-electric cells giving rise to audio-frequency currents which can be amplified and fed to loud-speakers. Sound tracks are of two types, variable density and variable area. The first of these types is produced by a light beam of constant width but variable density. A light beam modulated in this way is produced by a glow lamp with a suitable current passing through it. As a rule this method gives insufficient light, so now some form of mechanical light valve is used. If the sound-track of the reproducer is opaque, there is very little background noise, but if it is clear, noise will arise due to dirt, grain and scratches interrupting the light. Recent developments in sound recording are mainly due to methods of getting rid of this noise.

The Metadyne in Electric Traction

THE 'metadyne' is a new form of electric machine utilizing the principles on which both the dynamo and the motor work. The currents in some of the windings of the armature tend to produce rotation in one direction and the currents in others tend to produce rotation in the opposite direction, the object in view being to get rapid acceleration when starting and rapid retardation when stopping. The great advantage of the metadyne is that when going at speed it can be pulled up rapidly by utilizing some of its own kinetic energy of motion without drawing on electric power from the electric supply line as,

for example, when a mechanical brake is applied. Used in traction when trains are frequently starting and stopping, this leads to a considerable economy in the cost of the power expended. The metadyne was invented a few years ago, and developed in a number of devices applicable in practice for various purposes by J. M. Pestarini, now of the University of Turin. In a paper read to the Institution of Electrical Engineers on February 23 by G. H. Fletcher and A. Tustin, its application to electric traction on suburban railways was specially considered. After preliminary experiments, the London Passenger Transport Board placed an order for fifty-eight metadyne equipments with Metro-Vickers, all of which are now in constant service. It was found that at 3 m.p.h. per second (average) the speed was too high to permit of full braking being obtained on the 'motored' axles as the limit of adhesion of the wheels was exceeded. It was found necessary to apply air-brakes to the 'non-motored' axles at the same time as 'regeneration' was applied to the motored axles. During normal braking, approximately two thirds of the total braking effort is applied through regeneration and one third by air brakes. The metadyne principle was first applied to the Diesel electric shunting engines on the Paris-Orléans line and was most successful.

Corrosion of Underground Cables

MODERN telephone systems utilize extensive networks of bare lead-sheathed cables drawn into earthenware conduits, and although lead is one of the least corrodible of metals, as witnessed by the fact that many lead roofs exist which are five centuries old, and that the Romans employed lead water pipes some of which are said to be in use to-day, yet the replacement of corroded telephone cables costs the Post Office £50,000 per annum. In a paper read to the Institution of Electrical Engineers on March 8 by W. G. Radley and C. E. Richards, of the Post Office Engineering Research Station, it is stated that laboratory examination of samples of corroded sheathing, together with chemical analysis of the corrosion products and soil waters enable definite conclusions to be reached as to whether there has been electrolytic stimulation by stray currents or not. Useful information has been obtained from apparatus recording the sheath current at two points a short distance apart and accurate determination of the small potential difference existing between a sheath and its immediate surroundings. Localities exist, chiefly in certain provincial cities, where corrosion due to tramway stray currents is very rapid. There are also areas in rural districts, chiefly in south-east England, where the soil water is so rapidly corrosive to lead that it is now the normal practice to install these cables with some form of protective covering. The non-metallic cable sheath which has been discussed for a number of years does not yet seem to be within the realms of early possibility. Advantages are to be gained from the liberal application of a suitable cable lubricant. Considerable increase in the life of Post Office cables subjected to chemical corrosion has resulted from the addition of a silicate inhibitor to the petroleum jelly used as a lubricant. The success that has been attained has in nearly every case been due to the formation of a local 'electrolysis committee' for considering all the underground services—gas, water, electric light, telephones, etc., within the area.

The Enzyme System of Trans-Amination, its Mode of Action and Biological Significance

By Prof. A. E. Braunstein, The A. M. Gorky All-Union Institute of Experimental Medicine, Moscow

THE reversible transfer of amino groups between aminodicarboxylic acids and α -ketoacids, or 'trans-amination', reported in a series of papers by me and my associates¹, is of almost universal occurrence in biological objects. It is readily effected by most animal tissues², and also, as shown in this laboratory³ and independently by Virtanen⁴ and Euler *et al.*⁵, by vegetable tissues and micro-organisms. Trans-amination is effected by a special group of intracellular enzymes, for which the name *aminopherases* is suggested (in preference to the clumsy although more precise term aminotransportases). As trans-amination involves intermolecular oxidoreduction, the aminopherases should be classed among the deamolases. They differ in mode of action and in many properties from the formerly known enzymes of amino acid metabolism, including the *L*- and *D*-deaminases and specific glutamic and aspartic dehydrogenases.

The process of trans-amination can only take place with the participation of a dicarboxylic α -amino or α -ketoacid, functioning either as a stoichiometrical reaction partner (donator or acceptor of amino groups) or as a catalyst, or intermediate carrier of amino nitrogen, rendering possible the enzymatic shift of NH_2 -groups from amino- to ketomonicarboxylic acids. In the latter case, that is, in the presence of low concentrations of the dicarboxylic carriers, trans-amination is competitively inhibited by saturated dicarboxylic acids (oxalic, malonic, glutaric, adipic acid)⁶. All experimental data point to the special role in trans-amination of the two acidic groups in the dicarboxylic acid molecule. However, it is the peculiar electrostatic configuration, or polarity, of such a molecule, rather than the particular behaviour due to the presence of two carboxyl groups, that determines the availability of the substrate molecule for trans-amination. This is evidenced by the fact that α -amino acids similar in electrostatic structure to aspartic or glutamic acid but bearing, instead of the second carboxyl group, some other acidic substituent group (for example, phosphoserine, cysteic acid⁷ and homocysteic acid⁸), are adequate substrates for trans-amination, like the aminodicarboxylic acids. The formation of aminopherase-substrate symplexes evidently depends upon affinity of the enzyme to the two electronegative acidic groups of the substrate—most likely, due to the presence in the enzyme molecule of two electropositive basic groups forming a 'haptophoric' centre. Hence the inhibitory effect of simple dicarboxylic acids, displacing the amino- or ketodicarboxylic acids from the haptophoric centre. It follows that the substrates of trans-amination belong to two different types, namely:

(a) 'Primary' or 'active' substrates—those exhibiting direct affinity to the enzyme and capable of reacting with mono- or dicarboxylic partners alike. This type includes the natural amino- and ketodicarboxylic

acids (and some related acids, like mesoxalic, oxyoxosuccinic and α -ketoadipic acid⁹), as well as other dibasic acids such as phosphoserine, cysteic and homocysteic acid.

(b) 'Secondary' or 'passive' substrates—all monocarboxylic α -amino and α -ketoacids lacking direct affinity to the aminopherases and trans-aminated only as partners of the primary dicarboxylic substrates or with their intermediation in the case of catalysed trans-amination. The availability of secondary substrates depends upon the presence of a keto or free amino group in the α -position to a free carboxyl. β - or γ -amino or ketoacids, simple amines, aldehydes, ketones or hydroxyketones are inadequate; di- and tripeptides are not trans-aminated unless hydrolysed by contaminating peptidases.

There exist several aminopherases differing in specificity with respect to primary substrates. Two such individual enzymes have been obtained in cell-free solution, and purified to some extent, in this laboratory by Mrs. M. Kritzmann¹. One of these enzymes catalyses the shift of amino nitrogen from glutamic or to ketoglutaric acid; the other—more readily extractable from tissues and more labile—effects trans-aminations involving aspartic, resp. oxaloacetic acid. We propose the names *glutamic aminopherase* and *aspartic aminopherase* for the respective enzymes. (Preliminary experimental data indicate that our enzyme preparations react with some further primary substrates besides their natural ones: thus, glutamic aminopherase transfers amino nitrogen to mesoxalic and α -ketoadipic acid, whereas the specificity of the aspartic enzyme extends only to oxyoxosuccinic acid; phosphoserine, cysteic and homocysteic acid, while adequate as primary substrates in experiments with muscle pulp, are only secondary substrates for purified preparations of both aminopherases¹⁰). The aminopherases are optically selective: only the natural *L*-forms of the amino acids act as NH_2 -donators with aminopherase solutions, and the amino acids formed as reaction products also belong to the *L*-series (in whole muscle pulp a slight transformation of *D*-amino acids has been observed in some cases, but evidence on this point is not conclusive)¹¹.

The presence of aminopherases in most types of living cells suggests that they play an important part in nitrogenous metabolism, especially in the many tissues devoid of the enzymes required for direct formation and breakdown of aminomonicarboxylic acids (for example, muscle, brain, plant tissues). Several enzyme systems of wide distribution in various living tissues are known at the present, specifically and reversibly catalysing the synthesis and deamination of aminodicarboxylic acids (aspartases I and II, Virtanen's oxaloacetic oxime system⁴, glutamic and aspartic dehydrogenases). In association with such enzyme systems the aminopherases provide an adequate mechanism for the synthesis and

deamination of all amino acids in tissues containing no universal amino-oxhydrases. Ever since the first publications on trans-amination, I have pointed out the possible role of trans-amination in the synthesis of aminoacids in vegetable organisms, where the aminodicarboxylic acids apparently belong to the first organic products of nitrogen assimilation³. Recently, Virtanen⁴ and Euler, Adler *et al.*⁵ have reported experimental evidence supporting, though not conclusively proving, the role of the trans-amination mechanism in amino acid synthesis.

We wish to point out that the properties of *l*-deaminase (Krebs, Bernheim) indicate the complex nature of this enzyme and suggest that oxidative deamination of the *l*-amino acids is also probably due to the co-operation of aminopherases, glutamic or aspartic dehydrogenase and catalytic amounts of the respective dicarboxylic acids. Experimental verification of this hypothesis is in progress. If such be the case, it would follow that the dicarboxylic amino- and α -ketoacids function as intermediate carriers not only in the interconversion of amino acids by trans-amination, but also in their synthesis

from ammonia and deamination, thus forming a transition channel between mineral and organic nitrogen.

Summary.—The results of recent investigations concerning the transfer of amino-groups between amino- and ketoacids are discussed. These investigations led to the discovery of a new group of intracellular enzymes, termed aminopherases. A survey is given of the range of specificity and mode of action of these enzymes. The biological significance of the aminopherases and of the dicarboxylic amino- and ketoacids is discussed with a view to their probable role as key substances in the biological formation and breakdown of amino acids.

The Atmosphere as a Raw Material*

IN the middle of the seventeenth century, the phlogiston theory was generally accepted. Scientific study of the atmosphere only began in the last quarter of that century, and within fifty years of Stahl's formulation of the theory, it had been displaced, and oxygen had been recognized, isolated and identified. In little more than a century, the composition of air was known to 1 per cent, and not very long afterwards, Ramsay completed the story with his discovery of the inert constituents. At the present time, gases which are only present to the extent of one drop in 130 gallons are articles of everyday commerce.

Although use is now being made of the atmosphere as a raw material of industry, our demands are as yet quite unlikely to affect the stock appreciably. England and Scotland have twenty or more factories taking the oxygen from 20 million cubic feet daily, but this large amount ceases to seem dangerous when we remember that the population of those countries uses 600 million cubic feet daily in the ordinary course of respiration; animals add their demands to this figure, and the total is again vastly increased by the supply required for the daily combustion of wood, coal and petrol. The case is in marked contrast to that of coal. Mankind is continuously oxidizing carbon, and yet rapidly diminishing the amount of the only agent—vegetation—that can renew his exhalations to a useful atmosphere. The energy from sunlight received in a growing season by an acre of land is equivalent to that obtained by the combustion of 245 tons of anthracite. If 25 bushels of corn are reaped from the acre, they return energy equivalent to only 0.3 tons of anthracite. Nor is the prospect from water power very favourable. It is estimated that the hydro-electric power available

from the whole rainfall of America is about equal to the present power production from coal.

So far as the production of carbon dioxide by human beings is concerned, it is interesting to calculate that a man exhales about 3 lb. per day; a eucalyptus tree of the mountain ash type, 200 feet high and weighing 24 tons, is capable of breaking down about one third of this amount and returning the oxygen to the atmosphere. It is clear therefore that the tendency to replace vegetation of this type by buildings, or even by cereal crops, carries with it a potential danger to the oxygen supply.

It was about the year 1885 that man began to abstract oxygen from the air for its own sake, when the barium oxide process was first used commercially. At first, much of the oxygen was used for therapy, and for the limelight. Now that this is replaced by electric light, about 98 per cent of the oxygen prepared is used in engineering, either for metallurgical, fabricating, or cutting purposes. Of course, the oxygen is no longer extracted by chemical processes, but by liquefaction and subsequent rectification, in plants that can make 4,000 gallons an hour for days on end. The fractional distillation of liquid air depends for its success on the heat exchange tray devised by Kuhni, and known as a 'foam plate'. In it, a disk is built up in a true spiral, with about 10,000 holes to the square inch.

Turning now to the inert gases, argon is present to the extent of about 1 per cent, but was only detected in 1894 by Ramsay and Rayleigh. It is now separated directly in a state of comparative purity from commercial oxygen distilling apparatus. At the present time, about 10 million cubic feet are used annually to fill the 1,000 million electric lamps produced in the same time. Neon exists only to the extent of 1 part in 55,000, but its characteristic spectrum has led to the use of thousands of litres annually in 'neon lights' so widely used in advertising signs.

*Substance of the presidential address delivered to Section B (Chemistry) of the Australian and New Zealand Association for the Advancement of Science, by Russell Grimwade, O.B.E., on January 12, 1939.

Helium, present to the extent of one part in 245,000, or 50 tons in the atmosphere above each square mile of the earth's surface, is the lightest unflammable gas, and is thus of especial use in lighter-than-air craft. For this purpose it is collected from the gases of certain bore-holes in the United States, where it is present to the extent of 1-2 per cent. It is of particular value medically in that an artificial atmosphere of helium and oxygen can prevent Caisson disease or 'the bends', a malady, due to the solubility of nitrogen in human blood serum, to which divers and others working under increased pressure are subject. Krypton, occurring only to the extent of 1 part in a million, and xenon, only one tenth as abundant, are not used very extensively as yet, but the fact that they increase the efficiency of an electric lamp filament by 10 and 20 per cent respectively, suggests that they will eventually be in common use.

The remaining constituent of the atmosphere, nitrogen, constitutes 81 per cent of its volume. From about 1830, nitrogen was chiefly obtained from the caliche deposits in Chile, and the rate of extraction was so fast that in 1898 Crookes predicted a world famine in nitrogen, and therefore in agricultural products, at no very distant date. Within a very

few years, the situation was changed by the establishment of the first plant for the production of nitric acid from atmospheric nitrogen. That first process, depending on the electric arc, has now been superseded, first by the cyanamide process, and then by the Haber process, in which the immediate product is ammonia, instead of oxides of nitrogen. It is of interest to note that the arc process, with the production of oxides, is the one used by Nature herself as the main agency for restoring nitrogen to the earth's surface for agricultural needs; her arc is the lightning flash. In 1937 there were 145 plants operating on the Haber process, producing nearly 4 million tons of fixed nitrogen, an amount which, though large in itself, is only the amount to be found above 1/5 square mile of the earth's surface. In any event, the nitrogen withdrawn from the air almost all ultimately finds its way back again, through the agency of living matter.

From the consideration of these matters, we are eventually reminded that the balance of Nature is the only basis of man's existence. It will demand control over vegetation which has been lacking ever since the inception of the industrial period, and it is to chemists that the world should look for a lead.

Factor Analysis in Psychology

AT the general meeting of the British Psychological Society, held this year at the University of Reading, a symposium on factor analysis attracted on April 1 the largest number of members present for several years at any meeting of the Society.

Opening the symposium, Prof. Godfrey Thomson said that many sets of factors are mathematically available, and principles have to be adopted for deciding between them. These have included: (1) the universal desire to use few common factors; (2) reproducing the whole variance; (3) reproducing the correlations; (4) insistence on a general factor; (5) rotating to psychological significance; (6) requiring 'simple structure'; (7) requiring invariance of analysis; (8) requiring reciprocity of persons and tests. The second loses least information, but conflicts with (5) and (7). The third principle is used by both the Spearman and Thurstone schools; the former proceeds step by step, the latter by a simultaneous analysis. The Spearman school safeguards psychological significance at each step, and insists on a general factor. The Thurstone plan rotates the factors into 'simple structure' and holds that psychological significance will ensue. 'Simple structure' seems to rule out a general factor, and Thurstone finds no g in Spearman's own g -tests. Both methods result in large specific factors, and have more factors than tests, so that the factors cannot be accurately estimated. The last principle (8) is put forward by Burt, who analyses covariances. His reciprocity is only obtained, however, after removal of a factor composed of the average.

Prof. Spearman's paper, read by Mr. Maxwell Garnett, directed attention to the disappearance of the general factor in Thurstone's 'Primary Mental Abilities'. A set of correlations, he said, can be factorized in many ways, the choice being regulated

by statistical simplicity and psychological interest. The theory of two factors uses a method which draws all the correlations from one factor. Statistically simple, it affords psychologically the basis for the concepts of general ability. Hotelling, Kelley and Burt, in securing that the weights of factors are heaped up in order of calculation, generate negative loadings which contradict experience. Alexander and Thurstone, in rejecting negative loadings, decrease without eliminating the indeterminateness. Thurstone in addition maximizes the number of zeros. It is this which banishes the general factor, for weights which fall below a certain minimum are ascribed to error and counted as zero. Moreover the number of Thurstone's factors creates suspicion.

Correlations alone fail to determine factors completely: other grounds are needed. In the special case of one single factor we have the cogent ground of parsimony; in all other cases to find adequate grounds is difficult.

Prof. Burt emphasized that the components obtained by factorizing a correlation table describe an analysis of the relations between minds and their environments. Whether a factor has meaning depends on the appropriateness of the experimental design as much as on the validity of the analysis. Factor analysis should, if possible, be based on covariances rather than on correlations. Variance varies objectively, and depends primarily on the complexity of the process measured. When the errors are sufficiently small, all analyses reveal a series of factors whose contributory variances are roughly 50, 12, 5 . . . per cent of the total. This may be explained by regarding factor analysis as a process of successive averaging. Concerning the 'sampling theory', he said that an effective test integrates a wide variety rather than samples a large number of co-ordinations.

Accepting Prof. Thomson's equation, it can be shown that the sum of the test-measurements operates as the general factor in his hierarchies. If we assume that intelligence depends on the number and systematic arrangement of the unorganized synapses of cortical neurones, this interpretation appears equally plausible from a physiological point of view. He reiterated his belief in the reciprocity principle and his opinion that the bipolar factors obtained by correlating tests and persons respectively are essentially identical.

Dr. W. Stephenson said that Prof. Thomson would appear to take tests for granted and to seek to identify the qualities of persons tested with selected factor axes. It seemed to him that tests should have something to say about the axes to be selected, and that we should define axes at the outset on psychological grounds. Mathematical theorems would then be used to see whether these axes are consistent with facts.

There is a great deal of equivocality in the use of the word 'ability' in factor analysis, and he proposed a definition which relates abilities to what he called *non-fractional* factors for cognitive activity, a *non-fractional* factor being a kind of compound of the 'fractional' factors usually discussed.

A general discussion followed the papers. In summing up, Prof. Godfrey Thomson said that as Thurstone was not present he thought he ought to say something on behalf of the idea of 'simple structure'. Recently he had heard Prof. P. A. M. Dirac support the thesis that when he found a hypothesis or solution of great mathematical beauty he could have considerable confidence that it would correspond to something real in physical Nature. Something of the same sort, Prof. Thomson imagined, was behind Thurstone's faith in 'simple structure'.

On the other hand he felt that Prof. Spearman would have been justified in putting up a more fundamental defence of g than he had. For the blemishes criticized in Thurstone's work could be removed by care, and Thurstone might still attain 'simple structure' in chosen batteries. The real defence of g was surely that it had proved to be useful.

University Events

ABERDEEN.—On March 29, the honorary degree of LL.D. was conferred on the following among others: Prof. J. Gray, professor of zoology in the University of Cambridge; Dr. J. McIntosh, director of the Bland-Sutton Institute of Pathology, Middlesex Hospital.

The ordinary degree of D.Sc. was conferred on Dr. J. S. McPetrie for a thesis entitled "Studies in the Production and Propagation of Radio Waves".

CAMBRIDGE.—Dr. O. M. Solandt, of Trinity Hall, has been appointed University lecturer in mammalian physiology.

N. B. Slater, of Gonville and Caius College, has been appointed second junior observer at the Solar Physics Observatory.

Sir Edward Mellanby, of Emmanuel College, secretary of the Medical Research Council, will deliver the Rede Lecture at 5 p.m. on April 28, the subject of which will be "Some Social and Economic Implications of the Recent Advances in Medical Science".

Science News a Century Ago

The Royal Society

At a meeting of the Royal Society on April 11, 1839, James Finlay Weir-Johnston (1798-1855), the agricultural chemist, read a paper "On a New Equi-atomic Compound of Bicyanide with Bin oxide of Mercury". In the paper he gave an account of the properties of "a salt, obtained by agitating, with red oxide of mercury, a small portion of hydrocyanic acid, and which he found to be distinguished from the bicyanide of mercury by its sparing solubility in cold water, by the alkaline reaction exhibited by its solution (a property which indicates an excess of mercury) and by its susceptibility of detonation by heat, depending on this excess being in the state of an oxide and on the carbon of the cyanogen it contains, and the presence of which is shown by the disengagement of hydrochloric acid gas when acted on by hydrosulphuric and hydrochloric acid".

At the same meeting Felix Savart (1791-1841), the successor of Ampère at the Collège de France, Macedoine Melloni (1798-1854) the Italian physicist, and Lambert Adolphe Jacques Quételet (1796-1874), the Belgian astronomer and statistician, were elected foreign members.

Lacaille's Astronomical Observations at the Cape

On April 12, 1839, the concluding part of Thomas Maclear's paper "On the Position of Lacaille's Stations at the Cape of Good Hope" was read. The lapse of 85 years since Lacaille's visit had obliterated all local evidence of the French astronomer's operations, and the fact that he had been there at all was only kept alive by the inquiries of Captain Everest in 1821. Having by inquiries found the house Lacaille resided in, Maclear measured the position of the house relative to the Royal Observatory by triangulation. He then proceeded to discover the exact site of Lacaille's northern station at Klyp-Fonteyn. With the assistance of a party from the Royal Engineers he made excavations of various ruins and so unearthed the foundation of the granary used by Lacaille.

Geology in Russia

"Some idea of the activity of the Russians in pursuit of science, but especially that of geology," said the *Athenaeum* of April 12, 1839, may be gathered from the following statements. "The Inspector in Chief of Mines, the Count Cancrini, has for several years obtained his Imperial Majesty's permission to make geological and mineralogical researches in various parts of the vast empire, and a scientific committee has been established to superintend the publication of a work entitled 'Annals of the Russian Mines'. M. Parrot, Professor at the University of Dorpat, was ordered by the Russian government to explore Armenia and Transcaucasia. . . . M. Kupffer has determined the height of the Elbrous, the culminating point of the Caucasian chain, and is at this moment making meteorological and magnetic observations throughout the Empire. Baron de Humboldt and M. Rose have traversed the northern mountains, M. de Pasch has described the chalk formations in the south of Poland, M. Pander those of the neighbourhood of St. Petersburg. . . . M. de Semanoff, principal engineer of mines, has described the geological formation of the northern part of the Altai Mountains."

Societies and Academies

London

Royal Society (*Proc.*, A, 170, 1-144; 1939).

I. LANGMUIR: Molecular layers. (Pilgrim Trust Lecture).

T. SVEDBERG and others: The protein molecule (Discussion).

W. E. GARNER and A. J. HAM: Combustion of methane.

E. E. SOHNLEDER, C. F. GOODRICH and R. J. LYTHGOM: Spectral variation of the photosensitivity of visual purple.

W. G. PENNY and G. J. KYNCH: Magnetic susceptibility and related properties of rare-earth crystals.

J. J. BICKERMAN: Formation and structure of multilayers.

Paris

Academy of Sciences (*C.R.*, 208, 685-776, March 6, 1939).

E. ESCLANGON: Dynamometric forces and field forces.

H. VINCENT: Pathogenic characteristics of the micro-organisms of gas gangrene; fundamental principles of anti-gangrene serotherapy.

C. BENDICKS: Remarks on the generation of parallelopipeds of n dimensions.

S. BERGMANN: Approximation of functions satisfying a linear equation with partial derivatives.

F. ROGER: A classification of extremals.

E. HALPHEN: Convergence of estimations.

G. PÓLYA: Integral interrupted series which are not extensible.

G. VALIRON: Riemann surfaces defined by certain integral functions.

M. ZORN: Abstract theory of analytical functions.

H. CARTAN: Solution of Carleman's problem for a closed finite integral.

J. DUFRÉNOY: Meromorphic functions in an angle.

A. OUDART: Problem of wakes; validity of solutions.

J. K. DE FÉRET: Spectrum of homogeneous turbulence.

M. LUNTZ: Isotropy of turbulent movements and the distribution of energy between translation and rotation.

L. SACHMANN: Singularities in the study of a model wing.

H. FARR: Gaps in the asteroid ring considered as resonance phenomena.

H. MINCHY: An anomaly of the solar period. 1923-33. This period showed 5-6 years of increasing activity followed by 4-5 years of decreasing activity; generally the period of decrease is greater. (The same phenomena occurred in 1723-33 and 1823-33, confirming the author's previous suggestion of a 100-year cycle of 9 periods of 11.1 years.)

J. LAGRULA: New measurements of the intensity of gravity in the Departments of Algiers and Constantine.

F. CARBENAY: High-frequency telephony along triphase power transport lines.

G. FOIX: Constant paramagnetism of tetravalent cerium and of other ions having the same number of electrons as the rare gases.

P. LAMBERT and J. LECOMTE: Absorption of acrolein in the infra-red spectrum.

C. MAGNAN: Disruption of the nuclei of elements lighter than uranium, under neutron bombardment. Positive effects were obtained with gold, tungsten and titanium.

J. THIBAUD and A. MOUSSA: Disruption of uranium nuclei under the action of neutrons, and the liberation of energy which results. Chemical separations suggest that an isotope of bromine is formed.

A. BOUTARIC and Mlle. S. THÉVENET: Viscosity of arsenic sulphide sols and Einstein's formula.

W. S. REICH: Separation of oces by chromatography of their coloured esters.

E. DARMOIS, Y. DOUCET and Mlle. M. MURGIER: Cryoscopy of molybdic acid in aqueous solution.

G. DÉJARDIN: Red bands of cyanogen in the spectrum of the night sky.

R. GRANDMONTAGNE: Remarks on the variation of colour of the night sky. During 1938, radiation at the beginning of the red, 5850-6800 Å., was particularly weak from March to August.

S. MAELOUM: Analysis of the components of the Euphrates in Syria.

J. BOURCART: Origin of the silts of the maritime Seine.

B. RAJČEVIĆ: Salinity of the waters of the Seine between Amfreville and Honfleur.

C. FRANÇOIS-BOUF: Variations of salinity, during a day in September, of the waters of the maritime Aulne at Trégarvan.

R. LAMT: Conditions of illumination of some algae living in the grottoes and littoral defiles of the Falkland Islands.

L. GAILLEN: Hypophysectomy and the sexual cycle of *Rana temporaria* L.

P. MINIER and C. BLANCPAIN: Quantitative determination of the antineuritic vitamin in natural media; new technique.

P. BOQUET: The role of copper in the attenuation of viper venom (*Vipera aspis*) by hydrogen peroxide.

Mlle. R. SCHOEN: Transmission of the Nicolas and Favre malady by nasal instillation in the white mouse.

A. STAUB: Vaccination against swine fever.

Dublin

Royal Dublin Society, February 21.

A. G. G. LEONARD and BRIDGET McVERRY: Atmospheric pollution in Dublin during the year 1938. Measurements of atmospheric pollution including suspended impurity and estimations of sulphur dioxide have been carried out continuously near the centre of Dublin for the year 1938, and are compared with records published for English cities for 1937.

O. ROBERTS and S. A. STYLES: An apparent connexion between the presence of colloids and the osmotic pressures in conifer leaves. There is good agreement between the osmotic pressures of conifer leaves as determined by the plasmolytic and cryoscopic methods when the leaves in question are colloid-free. In conifer leaves which contain mucilaginous colloids and have slimy or viscous saps, there is a wide disparity between the results by the two methods. The cryoscopic results agree with the others in the literature, but the plasmolytic osmotic pressures are always very much higher.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

HEAD OF THE ENGINEERING DEPARTMENT, Luton Technical College—The Principal (April 15).

PRINCIPAL of the Bengal Engineering College, Shibpur, Calcutta—The High Commissioner for India, India House, Aldwych, London, W.C.2 (April 17).

LECTURER IN PHYSICS in the Battersea Polytechnic, London, S.W.11—The Principal (April 21).

JUNIOR SCIENTIFIC OFFICERS in the Electricity, Metrology, Engineering and Aerodynamics Departments of the National Physical Laboratory, Teddington, Middlesex—The Director (April 24).

LECTURER IN THE HYGIENE AND PUBLIC HEALTH DEPARTMENT of the Battersea Polytechnic, London, S.W.11—The Principal (April 29).

PRINCIPAL of the Beaufort Institute, S.B.11—The Education Officer (T.I.), County Hall, S.B.1 (May 1).

ASSISTANT DEMONSTRATOR IN PHYSICS (Woman) in the Royal Holloway College, Englefield Green, Surrey—The Principal (May 1).

JUNIOR RESEARCH PHYSICIST for the National Research Council of Canada, Ottawa—The Secretary-Treasurer (May 15).

UNIVERSITY READER IN MECHANICAL ENGINEERING in the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, W.C.1 (May 17).

Education in a Democracy

A HOPEFUL effect of the challenge thrown down to democracy in the crisis of September last and in the events which have followed is the turning back to the beliefs and principles upon which our liberties are founded, and which are our justification for holding them and the frank facing of the issues involved. Men are freely recognizing that if the democracies are to withstand the challenge of the totalitarian regimes, with their threat to so much of the noblest in our heritage, it can only be as they prove themselves inherently superior and able by force of example as well as precept to check the ruthless doctrines which threaten alike the peace of the nations and the liberties of individuals. The survival of democracy depends on its ability to make constructive contributions in the present and future, not merely on its achievements in the past.

An admirable example of this tendency is to be found in the question of education, and especially education for citizenship. The certainty of aim of education under any form of dictatorship is a challenge to the educational systems of democratic countries which cannot be ignored. These systems produce citizens who believe the doctrines which their rulers wish them to believe, and are imbued with a fierce nationalism and devotion to the State. If we repudiate the charge that democratic systems produce pupils whose knowledge is unrelated to their country's needs, and whose minds are adapted for argument but not for loyalty or constructive criticism, we may fairly be asked what purpose or set of principles we have to set up against those of the authoritarian regime.

This, indeed, is a central problem of democracy to-day. It is an element of almost every question

of national defence or preparedness for war, and the choice between a compulsory or voluntary national register will probably be determined by our efficiency in solving this problem. Essentially we require to define good citizenship in a democracy, and to show how education can escape being an aimless pursuit of facts without becoming an instrument of propaganda. A significant section in the Spens Report points out that on the extent to which the youth of Great Britain can be fitted to fulfil later their duties and to take advantage of their opportunities as citizens of a democratic State may well turn the whole future of democracy, and the report emphasizes the need for conscious effort by teachers at every point to use their opportunities.

An admirable discussion, by Michael Stewart, of the fundamental problem has been issued under the auspices of the Association for Education in Citizenship.* Under the title "Bias and Education for Democracy", Mr. Stewart gives us a highly suggestive and stimulating discussion of matters which are as relevant to the question of preserving freedom of thought and exposition as to teaching, and the wise and effective use of the opportunities which science no less than other subjects affords for training in citizenship.

Sooner or later, the difficulty of propaganda crops up, and Mr. Stewart meets it by a frank and careful analysis which deserves the attention of scientific workers, whether primarily concerned with the social sciences or not. He discriminates between two types of propaganda. The first, non-rational propaganda, aims at securing acceptance for certain views by appealing to the emotions and neglecting the reason, and sometimes

* Oxford University Press.

by vilifying opponents. This type is not confined to politics: much advertising material, though free from scurrility, is of this type, and whether in advertisement or in politics is frequently due to bias in the mind of the propagandist. While, however, propaganda may be a justifiable activity, biased judgment is at all times to be avoided, and it should not be confused with the deliberate selection which must be practised in teaching no less than in art or in science.

Rational propaganda, on the other hand, seeks support for a given view by marshalling reasoned arguments in its support, and fortunately there are both politicians and advertisers who use this method. Although its object is to serve a cause, it will not express opinions without examination of the facts so far as its time and ability permit. Where rational arguments are employed to propagate beliefs which represent the experience of the race, the resulting activity is certainly part of education and we might hesitate to call it propaganda. A sound principle may, however, be advocated by inaccurate or dishonest methods with results no less disastrous than attempts to propagate controversial views by rational methods.

Mr. Stewart accordingly stresses the danger of using ordinary lessons to propagate controversial opinions, even by rational methods, and in regard to the impartial presentation of controversial subjects stresses the need for handling such matters in a realistic way, even while excluding rational propaganda. He asserts indeed that this is the subject problem of the social sciences. Just as the teacher of chemistry, by putting acids and explosives into his pupils' hands, has an opportunity for training them in sensible conduct, so it is a positive advantage of the social sciences that they promote clear and unprejudiced thinking on disputed topics.

In the early stages of education some statements must be presented authoritatively as statements of fact; but even among beginners the use of authoritative statement has its dangers. A community which transmits its rules of conduct solely by authoritative teaching will make no progress towards a sounder moral judgment, and Mr. Stewart directs attention to possibilities in the use of broadcasting, the film, and dramatic work, as well as in the use of books which might make the promotion of right conduct attractive and interesting. The development of the critical process should begin at a comparatively early stage in education with the teacher's aid.

Especially are the social sciences important as vehicles for such training. From the study of human motives and actions in the past, the pupil sees that wisdom and honourable conduct are not the monopoly of those who hold a particular set of opinions. He becomes aware of the need for intellectual honesty and learns the nature of fair argument, and the difference between sound and unsound methods of proof. The power of rational criticism can, of course, be developed in many other subjects, such as the natural sciences. Dr. Thouless and Mr. Jepson have shown how accurate thinking can be taught at school, and Dr. Thouless ("Education for Citizenship in Secondary Schools", chap. xvi, p. 235) emphasizes that one object must be to create citizens intelligently approaching the problems of their citizenship and not young logicians or psychologists.

The essential point is that reasoning powers should be used not only to appraise the value of arguments, but also to handle facts and, if excessive effort is spent in encouraging criticism, education may produce only sceptics or persons without the power of decision. Life demands action as well as belief, and scepticism, if a necessary part of education, is by no means the only part. The pupil must learn how to act as well as to think for himself. Accordingly, Mrs. Wooten (*Adult Education*, Dec. 1937, pp. 96-7), in a plea for constructive teaching, urges that for a teacher to discuss any practical problem without, in the end, indicating what he himself thinks the best way of tackling it, is incompetent and irresponsible teaching.

Discussing the value of particular subjects in this respect, Mr. Stewart points out that, in teaching natural science, the social and economic effects of scientific discovery should be considered. Discussions on the effects of mechanized production on wealth and employment, and on the military use of scientific research, are often conducted by people who have little knowledge of the real possibilities. It should be the function of the teacher of science to remedy this defect. At least, he can equip his pupils to avoid the more serious errors of fact and reasoning, and can help them in the search for evidence. Science should be treated at the outset as a body of knowledge by which mankind can help itself.

Once again we encounter in this discussion the importance of training in the citizen's own language. Unless he can express himself clearly and attractively, a citizen cannot make a contribution

to public life commensurate with his abilities. The purpose of democratic education, moreover, is human welfare, and this it is that dwarfs the narrow purpose of totalitarian education. Whatever impetus the enthusiasm of the dictatorship may give to society at first, there is no continuous springing up of new thought to give society flexibility and the power to adapt itself to changing circumstances. Influences which preserve society and sweeten life are cut off, and the State has no inherent principle of virtue.

The democratic citizen has the privileges and responsibilities of freedom; he is required to decide public policy and accept the consequences of his choice. Only in democracy can the teacher whole-heartedly see that his pupils get so much enjoyment from using their minds that they will not fear responsibility. Moreover, the teacher in a democracy must not fail to point out the mistakes of democracies in the past, whether the denial of elementary rights to subject peoples or the failure in foreign relations to accord to other nations the

consideration and justice which their citizens displayed to each other at home.

Failure to understand that freedom means responsibility has brought about sloth and corruption which have paved the way for dictators, and scientific workers are no more free from responsibility for such failures than other classes of their fellow citizens. Mr. Stewart's lucid analysis of bias and propaganda indicates the causes of some of the defects in the teaching and exposition of science and the failure of scientific workers to make their full contribution in the solution of social and economic problems. At the least, it may be hoped that this admirable pamphlet will arouse them to a sense of the opportunities and responsibilities which are theirs, whether as citizens or as teachers of science, and to the resolute action which is demanded no less in the interests of scientific advance itself than in the safeguarding of those rich values of civilization which we owe to the freedom of thought and speech and criticism inherent in democracy alone.

The Botany of Crop Plants

Introduction to the Botany of Field Crops By Prof. J. M. Hector. (South African Agricultural Series, Vol. 16.) Vol. 1: Cereals. Pp. xii + 478 + xiii-xxxiv. Vol. 2: Non-Cereals. Pp. viii + 479-1128 + ix-xxxiii. (Johannesburg: Central News Agency, Ltd.; London: Gordon and Gotch, Ltd., n.d.) 70s. net.

THE plants making up the miscellany known as 'field crops' are distributed throughout the families of the flowering plants almost haphazard. The qualities which make them valuable in industry or as food for man or stock, such characters as the production of fleshy roots or shoots, starchy or oily seeds, long fibres, etc., are usually of little or no importance to the botanist tracing phylogenetic relationships (although when correlated with wider ecological and soil studies they may be of fundamental interest) and, in consequence, the study of field crop plants has been seriously neglected by academic botanists.

During the last three decades, however, the study of field crops has been taken up by agricultural botanists, more especially in the United States, Germany and the U.S.S.R., but notably in Great Britain by Percival, and of many crop plants we now have a greater knowledge than of

many plants of more theoretical interest. Much of this knowledge is of such a character that it could usefully and justifiably be incorporated in the pure botanical curriculum and the agricultural plants used as bases of study. If principles can be equally well exemplified in plants of great economic importance, it is surely better to use those plants in teaching than traditional examples of little or no human value.

Prof. Hector has aimed at surveying certain aspects of this field of work and, in his two imposing volumes, has presented in co-ordinated form a vast amount of information leading to an understanding of the nature and life processes of crop plants. His range covers field crops important as food for man or beast or valuable as producing economic fibres but, with the exception of the hop grown for brewing, he does not touch upon beverage plants or, with the exception of tobacco, upon medicinal and drug plants. Vol. 1 is devoted entirely to the Gramineae, including the various temperate and semi-tropical cereals and sugarcane, but excluding pasture and other cultivated grasses. Vol. 2 covers a very wide field: the various root and cole crops, fibre plants such as hemp, flax and cotton, leguminous and other forage and oil-seed crops, and various oddments such as

onions, asparagus, tomato, pumpkins and cucumbers, and a few salad plants.

The author's point of view throughout is botanical and not agricultural, and he confines his attention to the developmental anatomy, reproduction, systematics and cyto-genetics of the plants: there is nothing of ecology, physiology or pathology. Perhaps more attention might, with advantage, even accepting the author's restriction of boundaries, have been given to description and illustration of the plants themselves and their developmental stages as met with in the field: the author assumes a familiarity with them in his readers which many may not possess. The amount of detail in the book is enormous, and, if one were to abstract and combine related portions, one would have a series of fairly compendious monographs on the anatomy, genetics, etc., of agricultural plants.

Such a *magnum opus* could not on its publication be up to date, but here and there, as for example in the section on the sugar beet, the book is seriously out of date. In fact, the entire chapter on the Chenopodiaceae, as well as those on the Cruciferae and Leguminosae, provide many grounds for cavil. The author does not claim to deal adequately with the literature after 1935, although a few 1936 references are included in the bibliographies, and a few of 1937 are inserted as textual footnotes. There are, however, some striking omissions in the period 1930-35: for example, the author devotes ten pages to a discussion of the root nodules of the Leguminosae, but does not refer to the work of Virtanen or to the fine monograph published in 1932 by Fred, Baldwin and

McCoy. Considering, however, the wide field covered by the author, serious lapses are rare, especially in view of his statement "that there is marked difficulty in obtaining certain literature in the Union of South Africa". The author index to each volume includes about a thousand names and, as references are cited in full at the end of each chapter, the book is a splendid introduction to the literature of the subject.

One or two points of criticism may perhaps be made. The volumes are illustrated by 448 text-figures nearly all copied from other publications. Often the figure is enlarged from the original so that crudities of drawing which did not show in the original figure are badly exaggerated in the reproduction, or where half-tones have been used the reproduction is poor and often obliterates any detail of the original illustration. Further, the "Contents" of each volume is a single page list—Ch. IV. Wheat Species (*Triticum*); or Ch. XVII. Leguminosae. But there are, for example, 121 pages devoted to wheat, and 168 to legumes, each a book in itself, and although main headings are in heavier type and one can, of course, always refer to the excellent plant and general indexes at the end of each volume, yet a synoptic "Contents" would have made the book much easier to use.

By and large, however, one has little but admiration for the author's achievement. He has digested and co-ordinated a wealth of information from all countries, including much Russian work, and has clarified this in the light of his own researches and experience. His book will be useful to agricultural botanists the world over.

W. B. BRIERLEY.

The Psychology of Society

(1) Social Psychology

By Prof. Daniel Katz and Prof. Richard L. Schanck. Pp. xiv + 700. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1938.) 18s. 6d. net.

(2) The Psychology of Social Movements

a Psycho-Analytic View of Society. By Dr. Pryn Hopkins. Pp. 284. (London: George Allen and Unwin, Ltd., 1938.) 10s. 6d. net.

VERY different approaches to the psychology of society are presented by the two books under review.

(1) The strength of Dr. Katz and Dr. Schanck's text-book on social psychology lies in its detachment and impartiality. The authors make a careful and critical analysis and classification of

the problems of conformity and non-conformity within social groups; the question of the motivation of behaviour, and the mechanisms of social interaction; the psychology of individual differences, illustrated by the clinical study of personality; and the problems arising within a group, as the complexity of the structure of the group increases.

Much experimental work is summarized and used to illustrate and to support the points developed from theoretical analysis; but it is inevitable that the strength of the book should contain its weakness. The problems of unemployment, delinquency, making two ends meet, betting and gambling, and so on are omitted. They are problems that it is almost impossible to analyse as impartially as those with which the authors are

concerned—such problems, for example, as the analysis of types of conformity into oenotropes, folkways, institutional ways, fads and fashions, etc. Yet some place in a text-book on social psychology should perhaps have been found for them. That, however, is not the orientation of this text-book, but what it sets out to do it does admirably and with a wealth of detail.

(2) No one could accuse Dr. Hopkins of avoiding topical issues or of being too detached. He discusses sadism and war, the acquisition of property, marriage and birth control, smoking and religion. The explanation of these social phenomena he finds in oral and anal eroticism, the oedipus complex, and, occasionally, homosexuality. His line of argument may be illustrated by his view that the most important element in war is the oedipus complex. The enemy is identified with the evil father-figure, and our repressed desire to kill our father may be let loose on the enemy. Similarly, our country is identified with our mother, and when foreign troops threaten her we describe it as an act of invasion or of assault. In extension of this view, Dr. Hopkins mentions that all the allies in the Great War "felt outraged by the rape of Belgium".

While the oedipus complex is not regarded as the sole determining factor in the social psychology of war, it is held to be the most important. Now although there might be some reason for identifying one's native land with one's mother, it seems to be stretching the point a bit for Englishmen to extend this identification to Belgium. Why should Belgium be regarded as the mother of Englishmen?

If the identification developed after we had been fighting for a while for Belgium, is it possible for a mother-identification to occur before we have fought for a country? Did the British, in fact, identify in turn Austria and Czechoslovakia with their mother last year? Then again, why should countries go to war if they refer to their native land as their fatherland or patria? Why do individuals show patriotism rather than matritism? Presumably, if Dr. Hopkins's view is correct, they should fight for their fatherland, so as to prevent him from being homosexually assaulted by the evil father-figure of the enemy. But if they are motivated by the oedipus complex, they ought to be only too pleased to see their father assaulted or maimed.

Similar logical difficulties in the way of accepting Dr. Hopkins's doctrines present themselves in the other problems he discusses. In all of them, in spite of his stimulating and persuasive presentation, there is so much substitution and identification and extension to be made to the original doctrine, that one who finds it sufficiently difficult to appreciate the full significance of the Freudian doctrine when applied to individuals, must fail to see the relevance to social psychology of some of the extensions which appear to Dr. Hopkins to be so obviously satisfactory. Dr. Hopkins would no doubt agree that one needs to be an analyst or to have been analysed before one can properly appreciate his book: to the uninitiated, many of the arguments must suffer from their apparent lack of logical consistency.

J. M. BLACKBURN.

Bio-meteorology

The Patient and the Weather

By Dr. William F. Petersen, with the assistance of Margaret E. Milliken. Vol. 4, Part 1: Organic Disease—Cardio-Vascular-Renal Disease, including a Chapter on Experimental Endocarditis, by Prof. Alexander J. Nedzel. Pp. xxxiv+663+19 plates. 10 dollars. Vol. 4, Part 2: Organic Disease; Hypo- and Hyperthyroidism, Diabetes, the Blood Dyscrasias, Tuberculosis. Pp. xxviii+729+22 plates. 11 dollars. Vol. 4, Part 3: Organic Disease; Surgical Problems. Pp. xxxvii+651. 10 dollars. (Ann Arbor, Mich.: Edwards Brothers, Inc., 1937-38.)

DR. PETERSEN'S *magnum opus*, as the title implies, deals with the effects of that most changeable of mundane things, the weather, rather than with different kinds of climate. In previous volumes (see NATURE, Jan. 16, 1937) he has

brought together a mass of observations showing its influence in a great variety of diseases. In the present ante-penultimate volume, in three parts, he discusses the operation of the same causes in another large group of diseases in which disturbance of the blood vessels and blood supply is the characteristic feature.

Great importance no doubt is attached to the possible influence of weather conditions on the heart and circulation, the main feature here described being the production of "pressor episodes", that is to say, a narrowing of the small vessels with resulting deprivation of oxygen (*anoxia* or *anoxemia*). The cardinal importance of the "basic variable in the oxidative mechanism" is here especially emphasized. Weather changes are of two kinds, producing (1) contraction, or (2) enlargement of the vascular bed, with, in each case, a

series of associated changes in the organism as a whole. These changes are accentuated at certain seasons and in certain climates. The seasonal influence in general is shown by the fact that the contractor, spastic and pressor effect (A R S phase) with relative alkalosis, is more common in autumn, and the enlargement or dilator effect (C O D phase) is most observed in the spring of the year. These are due to disturbances of the autonomic nervous function. In health, the recurring rhythm, A R S—C O D, is balanced and physiological. In numerous cases where this balance is unstable with, for example, a *tendency* to spasm and pressor episodes, as in many disorders of the cardio-vascular system, "meteorological damage" is very apt to occur.

Circulatory diseases especially are much influenced by meteorological environment. The medical reader may be reminded of the anginiiform symptoms which in many persons occur on exposure to slight changes of wind and temperature. Emotion, effort, tobacco, all contribute to pressor episodes, but the climatic factor is held to be more important. Coronary spasm is said to be most frequent in February and least so in August.

There is, in the author's view, clear evidence of a constitutional tendency to autonomic dysfunction, and that this is exhibited in a large group of apparently widely different diseases—ulcer of the stomach and duodenum, exophthalmic goitre, diabetes, urticaria, colitis, migraine and epilepsy. He has not noted a very common and suggestive observation, that many local climates, in winter resorts for example, are of a protective and sedative quality and so prevent or minimize 'pressor episodes' in a great variety of cases. Again, in hard climates and the winter season an artificial

compensative regime can be devised with excellent effect for the prevention of chills, as in the popular hot pithead baths.

It is known that many diseases, which are presumably due to specific invasions, may show a definite seasonal incidence. Rheumatic fever, which is associated with temperate latitudes, has a maximum incidence in the north-east American States in the late winter and early spring.

The author's argument in this volume may be expressed in a syllogism: cardio-vascular alterations enter into all diseases, even in surgical and mental crises; these alterations are especially conditioned by environment; all diseases are therefore more or less subject to environmental changes. He contends that the mechanism is always the same, the clinical expression variable without end. Above all, the human organism is to be considered *as a whole*. Many authors have stressed this doctrine (for example, Brugsch in his "Ganzheitsproblematik in Medizin"); the physiological balance of the whole spells health, its unbalance disease. To this end the body must be studied synthetically rather than organically. Lastly, the *biological rhythm* of the organism is well exemplified in autonomic peaks and troughs, the disturbance of which causes "the precipitation of disease".

It is impossible to draw conclusions as to the effect of change of weather upon patients from the experience of young and vigorous persons. Normal individuals in the prime of life find in the polar air mass with its fall of temperature, its pressor episode and resulting anoxemia, a powerful stimulant which fortifies their general resistance. For the weak and ailing, the same weather impressions may be disastrous, quickly followed by fatigue and failure of resistance.

The Land of Parrots

Australian Parrots:

their Habits in the Field and Aviary. By Neville W. Cayley. Pp. xxviii+332+27 plates. (Sydney and London: Angus and Robertson, Ltd., 1938.) 15s.

MR. CAYLEY a few years ago wrote a general guide to the birds of Australia which was followed by a more detailed work on the weaver finches, and now we have one on the parrots.

Of the thirty-seven species in Australia, nine are lorries, twelve cockatoos and the remainder true parrots. They range in size from the little budgerigar to the large black cockatoo, and many are very beautifully coloured. Australia, therefore, may be called the 'Land of Parrots'.

The large works of Gould and Matthews are beyond the pockets of most people and a well-illustrated book at a moderate price, such as the present volume, is very welcome. The discovery of each species is told in detail, and we realize how much Australian ornithology owes to Sir Joseph Banks. He sent George Cayley to collect plants in New South Wales and arranged for Robert Brown to accompany Flinders. Both collected birds in addition to plants, which were described by Vigers, Horsfield and others. Banks also encouraged the governor and officers of the young colony to take an interest in natural history, and one of them, we do not know who, employed Watling, the Scots convict, to draw birds and

animals. These drawings were sent to England and were seen by Dr. Latham, who made them known to science.

Just over a hundred years ago, John Gould landed in Australia to collect materials for his great work. He spent eighteen months in different parts of the country, discovered many new birds, and perhaps what was more important, made notes on different species in the field, which were afterwards reproduced in his volumes. Mr. Cayley quotes freely from these notes, and they are of much interest, as the status of many of the parrots has changed since Gould's day.

Flocks of certain species do harm to the crops of farmers and fruit growers, but on the other hand, we learn that both the yellow-tailed and red-tailed cockatoos devour quantities of forest pests. Parrots are generally considered arboreal, feeding on fruit and flowers, although quite a number of those in Australia feed on the ground and live on seeds of grasses and other plants. All lay white eggs and nest in holes in trees, with few exceptions. The rock parrots deposit their eggs in fissures or cracks in rocks, the night and owl parrots lay theirs on

the ground, and several of the smaller species form tunnels in termite mounds.

The distribution given is all too brief, and the maps showing the range of each bird might have been clearer.

The great majority of parrots in Australia are resident, some are nomadic, depending on the flowering trees and fruits, and at least three are migratory. The common budgerigar only visits the southern parts of the continent in winter, departing north again in February; while the little blue-wing and swift parakeets are summer visitors to Tasmania. The interesting night parrot appears to be extinct, but it may possibly turn up again like the paradise parakeet, which was lost for many years and then rediscovered. Several of the other smaller species are very rare and suffer from illicit trapping.

Mr. Cayley's plates are up to the high standard of his previous works, and in addition there are several other illustrations—reproductions of old drawings. Avicultural notes are given on each species, and Mr. Michin, of the Adelaide Gardens, contributes a chapter on parrots in captivity.

Alfred Brown : South African Naturalist

Gogga Brown :

the Life-Story of Alfred Brown, South Africa's Hermit-Naturalist. Told from his Journal by Prof. M. R. Drennan. Pp. xiii + 100 + 8 plates. (Cape Town : Maskew Miller, Ltd. ; London : John Clark, n.d.). 4s. 6d.

ALFRED BROWN was an Englishman who emigrated to South Africa in 1858. He there settled in the newly established town of Aliwal North, holding various minor offices in it until he retired on a pension, dying in 1920. He was an ardent and very successful collector first of fossils and eventually of stone tools, and for sixty years kept large numbers of lizards and tortoises in the garden behind the small cottage in which he lived. He observed the habits of these animals continuously and recorded his observations in the great diaries which formed the basis of Prof. Drennan's short 'life'.

Brown's early collections of fossils from the rather barren district round Aliwal North, were sent by him to Murchison, the more important specimens, a number of incomplete dinosaur bones, the first ever found in Africa, being described by Huxley. Unfortunately, Brown felt that he had been badly treated by these men, and sent his next consignment of fossil bones to Lartet in

Paris, and another to Vienna. Thus different parts of the same bone may now be found in three separate countries.

Some twenty years later, Seeley visited Brown and borrowed from him specimens which became the types of the Cynodont *Diademodon* and the Bauriomorph *Microgomphodon*. These remained in England and fifteen years later they and other specimens were presented by Brown to the British Museum (Natural History). About this time Dr. R. Broom called on Brown and succeeded in inducing him to allow him to describe further materials, including a great series of Triassic fishes from a locality which Brown would not reveal. When the present writer visited him in 1911, Brown produced still further materials which had not been seen by anyone, again from a secret locality. Finally, in 1920, the whole collection reached the South African Museum. But Brown's very large collection of implements lost all its value because the specimens became separated from their records.

The whole story is a pathetic one, a man of great intelligence and an ardent collector gradually becoming a recluse, a miser so secretive in all his ways that much of the value of his work was lost.

D. M. S. W.

Farm Machinery

By C. Culpin. Pp. 405. (London: Crosby Lockwood and Son, Ltd., 1938.) 18s. net.

A TEXT-BOOK on modern farm machinery by a British author was long overdue, and this book is a praiseworthy attempt to make good this deficiency. To-day there are few operations on farms to which machinery has not been applied, and an effort has been made to cover the whole field. In addition appendixes dealing with elementary principles of mechanics and prime movers have been added. These are well chosen, concise and clear.

The main subject is admirably marshalled but often details of design and operation are meagre; furthermore there is a lack of expression as to the true value of implements from the practical point of view.

One or two mistakes have been missed in proof-reading and there are some statements in working descriptions that need correction. At p. 170 the bills of the knotting mechanism are said "to grasp the twine between the loop and the sheaf". This is incorrect, but the correct version is given in note 3 to Fig. 87 (p. 173). In dealing with milk coolers (p. 269) it is stated that with water coolers the water runs in copper tubes covered with heavily tinned corrugated metal. There are no tubes in corrugated coolers, the water being in direct internal contact with the corrugations. At the foot of the same page we find that "the refrigerant cools a solution of brine which is then used for cooling the commodity". Brine is not used in farm refrigerating coolers; they work by direct expansion.

In conclusion, while admiring Mr. Culpin's courage and devotion to the subject in which he lectures, we think that if more than a bird's-eye view of the subject is to be attempted, the task is a composite one to be handled by specialists rich in both practical and theoretical knowledge in their own particular branches. Nevertheless, we welcome this book as an introduction to further study. C. E. E.

The Microscopical Study of Drugs

By Lillian A. Kay. Pp. viii+228+47 plates. (London: Baillière, Tindall and Cox, 1938.) 10s. 6d.

THIS book comprises a series of forty schedules, each designed to occupy a three-hour practical period, intended for students following courses of training in pharmacognosy where a knowledge of microscopy of drugs, starches, textile fibres, etc., is required. Introductory chapters deal with such fundamental subjects as the technique of drawing of microscopic objects, micro-measurement, maceration, and micro-chemical tests. Then follow directions for the detailed examination of surgical dressings, fabrics and organized drugs. Finally are given methods and examples of quantitative analysis of mixed and adulterated powders, and an appendix of useful information.

Practically all the above is already covered for students by Mr. T. E. Wallis in his "Practical Pharmacognosy". The chief advantage of Miss Kay's book lies in the illustrations, in which are set forth

the anatomical structure and histology of organized drugs prescribed for microscopical study in the syllabus of the Pharmaceutical Chemist Qualifying Examination of the Pharmaceutical Society of Great Britain. These drawings are generally faithful representations of what should be seen under the microscope, and will be appreciated by students, especially those who have not had the advantage of a sufficient botanical training.

Certain corrections will have to be made in a new edition, notably the references to the perimedullary phloem in the three solanaceous leaves, confused with the endodermis; and to the vascular bundles of fennel fruit, named primary ridges.

W. O. HOWARTH.

La Biologie des Orthoptères

Par Lucien Chopard. (Encyclopédie entomologique, Tome 20.) Pp. 542+5 plates. (Paris: Paul Lechevalier, 1938.) 250 francs.

THE name of Dr. Lucien Chopard is in itself a guarantee of the value and reliability of this work. It constitutes the most up-to-date and comprehensive account of the order of insects with which it is concerned. The work is arranged in thirteen chapters, each accompanied by a selective bibliography of publications relating to it. Chapter i deals with geographical distribution, which also takes into account insular faunas and distribution in geological periods. Reproductive phenomena occupy two chapters, and these are followed by chapters on development and activity, on sound-production, on autotomy and regeneration, and on reflexes and means of defence. Among other chapters, those on variation and heredity and on rudiments of social life are also noteworthy.

The book is a veritable storehouse of biological information and will prove valuable to workers in many fields. Its illustrations number 453 figures, all of which are clearly reproduced. The book is well supplied with both a general and an author index. A. D. I.

St. Thomas's Hospital Reports

Editors: Prof. O. L. V. S. De Wesselow, C. Max Page, assisted by N. R. Barrett, Dr. J. St. C. Elkington, Dr. A. J. Wrigley. Second Series, Vol. 3. Pp. 240+23 plates. (London: St. Thomas's Hospital, 1938.) 10s.

THIS volume contains thirty-nine articles from various departments of the Hospital, of which the following are examples: "A Complete Clinical and Pathological History of One of the Earliest Cases of X-Ray Carcinoma", by the late Prof. Leonard S. Dudgeon; "The Biological Test for Hodgkin's Disease", by Dr. D. P. King; "Vitamins in the Treatment of Rheumatism in Children", by Drs. H. W. Everley Jones and S. Taylor; "The Functions of a Psychiatric Department for Children in a General Teaching Hospital", by Dr. W. H. de B. Hubert, and "The Evaluation of the Modern Treatment of Gonorrhoea", by Dr. T. Anwyl-Davies.

The papers, which are well printed and illustrated, are all of a high scientific standard.

A Proposal to Redefine the Thermodynamic Temperature Scale: with a Parable of Measures to Improve Weights

By Prof. W. F. Giaque, University of California

IN several papers published between 1848 and 1854, Lord Kelvin¹ proposed the establishment of an absolute scale of temperature, based on Carnot's principle and "quite independent of the physical properties of any specific substance". On such a scale "the absolute values of two temperatures are to one another in the proportion of the heat taken in to the heat rejected in a perfect thermodynamic engine working with a source and a refrigerator at the higher and lower of the temperatures respectively".

The size of the degree used in connexion with Kelvin's thermodynamic scale is arbitrary. The natural way to define the size of the degree is also the easiest way and the one which best enables the widest attainment of accuracy, namely, to select *one* easily obtained and accurately reproducible fixed point, for example, a melting point, and assign to it a number such that degrees of the desired size are obtained. Unfortunately, this has not been done.

In practice, *two* fixed points are selected. The temperature interval between the freezing point and the boiling point of water is assigned some definite number of degrees, for example, 100 on the centigrade and 180 on the Fahrenheit scales of temperature. The above two points define the size of the degree and thus the number of degrees between the ice point and the absolute zero. As a consequence of this procedure, the values of the ice point and the boiling point of water on the absolute scale are frequently changed, depending on the experimental observations accepted as being the more reliable.

When an experiment is performed to measure a temperature by means of the fundamental criterion which Kelvin has pointed out, the final result contains not only the experimental error of the measurement itself, but also any error which exists in the particular value of the ice point which may have been adopted as the 'best value'. The value of the ice point on the absolute scale has been the subject of many investigations which certainly must be classed among the more accurate of scientific measurements. Nevertheless, even now the values of the several investigators vary by the larger part of the range 273.10° to 273.20° K., although an intermediate value may be selected which is almost certainly correct within two or three hundredths of a degree.

The *only* basic temperature scale defined with sufficient completeness to enable the determination of *any* temperature is the thermodynamic scale. For example, the centigrade scale gives the freezing point and the boiling point of water by definition and nothing more. If it were necessary, for example, to interpolate and extrapolate linearly, by means of such devices as those based on the expansion of liquids and gases, various thermocouples, resistance thermometers, etc., there would be little or no agreement as to the value of a given temperature. As a matter of fact, there is agreement only because the thermodynamic criterion of Kelvin is used in conjunction with the one hundred degree centigrade interval. Interpolation or extrapolation by means of the ideal gas law happens to be a convenient special case of the thermodynamic method.

The basic equations of gas thermometry may be written as:

$$T_{0^\circ\text{C.}} = \frac{100}{[(PV)_{100^\circ\text{C.}} / (PV)_{0^\circ\text{C.}}] - 1}, \quad (1)$$

and

$$T = T_{0^\circ\text{C.}} \frac{(PV)_T}{(PV)_{0^\circ\text{C.}}}; \quad (2)$$

where, in each case, PV is the product of gas pressure and volume corrected for gas imperfection. The T 's refer to the absolute temperatures.

In Equation 1 the per cent error in $T_{0^\circ\text{C.}}$ is 3.73 times that in the experimental ratio $(PV)_{100^\circ\text{C.}} / (PV)_{0^\circ\text{C.}}$, and this error is superimposed on the experimental inaccuracy involved in the determination of the ratio $(PV)_T / (PV)_{0^\circ\text{C.}}$ of Equation 2. Moreover, observations at the boiling point of water offer greater difficulties than do those at the melting point of ice, and thus contribute more to the inaccuracy of measurement of the ratio $(PV)_{100^\circ\text{C.}} / (PV)_{0^\circ\text{C.}}$.

The errors in temperatures on the thermodynamic scale which have their origin in Equation 1 may be eliminated by using the natural method mentioned above, namely, by defining $T_{0^\circ\text{C.}}$ as equal to a suitable number. It appears unlikely that a reference point more useful and satisfactory than the ice point can be found.

A proposal of this kind should be advanced only after a careful examination of its consequences. In this connexion, we ask the simple yet significant

question: Why is it important to know temperatures accurately in terms of any particular scale? For many purposes it would obviously be sufficient to refer temperatures to any arbitrarily adopted scale; for example, this would suffice to permit the reproduction of a desired set of conditions. It would also permit the accurate use of all energy considerations based on the first law of thermodynamics. However, even if one did not care to inquire further into the basic laws of Nature, there is no escape from their consequences, and it would be found difficult and inconvenient to represent certain important properties by simple equations; for example, the gas law would appear complex if data were obtained in terms of a linear interpolation on a thermometer based on the expansion of a liquid.

The insurmountable objection to an entirely arbitrary scale became evident when Clausius and Kelvin discovered the wide implications of the second law of thermodynamics, which requires the use of a temperature based on Carnot's principle. The use of this temperature leads to the simplest possible representations of all natural phenomena. In fact, all other temperature scales are forced to be as consistent as possible with the thermodynamic scale or they would long since have fallen into disuse.

In addition to the unnecessary inclusion of the experimental error in Equation 1 in the fundamental thermodynamic scale, there is a very common type of mistake that would be permanently eliminated by defining the value of T_{0C} . This may be illustrated by an example. Let us say that Laboratory A uses a value of $T_{0C} = 273.19^\circ \text{K.}$, whereas Laboratories B and C have decided that $T_{0C} = 273.13^\circ \text{K.}$ Each of these laboratories makes a determination of the boiling point of oxygen. Their results for the actual observed quantity, $(PV)_T/(PV)_{0C}$, are in exact agreement. A finds $T = 90.16^\circ \text{K.}$ but reports it as -183.03°C. whereas B and C find $T = 90.14^\circ \text{K.}$ and each reports -182.99°C. A calculation is carried out in a fourth laboratory that favours $T_{0C} = 273.19$ but the calculator accepts the value -182.99°C. because two observers have given it. As is practically always the case, the absolute temperature is required. The calculator obtains it incorrectly by adding 273.19 and -182.99 , which gives 90.20°K. in place of the correct 90.16°K.

The calculator may be accused of inexcusable carelessness, but it is quite probable that the literature failed to specify the reference T_{0C} , and abstractors are almost unanimously negligent in this respect. By way of analogy, the point we wish to make is that it is more sensible to remove a wire which circumstance has stretched across

a path rather than to continue avoiding it by what often amounts to the expenditure of considerable time. This type of confusion caused by emphasis given to the centigrade temperature scale approaches its limit when one laboratory may report an observation at -273.18°C. , whereas another laboratory says there are only 273.13 degrees below 0°C.

It is not our purpose here to discuss the various observed values of T_{0C} , but as mentioned above it appears probable that a value can be selected which will not differ from the true value by more than two or three hundredths of a degree. Thus a T_0 can be selected which will not disagree with the centigrade scale by more than one hundredth of one per cent. We know of no thermodynamic observations which are accurate enough to require a correction if a 'best value' of T_{0C} should be selected to define permanently the absolute scale of temperature. Thus no corrections to any existing literature would be necessitated merely because a best value of T_{0C} is adopted *permanently*.

It is not suggested that the centigrade scale be discarded, although, since its main advantages would appear to be only traditional and to permit the use of one less digit in representing ordinary temperatures, it might be desirable to substitute a scale with degrees defined as above but with the ice point taken as zero. At most, the difference between the boiling point and the freezing point on the two scales would not be found to differ by more than one hundredth of a degree, and until at least one experimenter succeeds in making thermodynamic measurements with an accuracy exceeding 0.01 per cent the difference may be ignored. If it should become necessary to make corrections for a few measurements of extraordinary accuracy, it would be a comparatively simple matter to do so.

It should also be made clear that while the thermodynamic criterion is regarded as basic, there is no suggestion of discarding such valuable secondary reference standards as resistance thermometers. It is obviously impractical to measure small temperature differences as accurately by direct observation with a gas thermometer as with a resistance thermometer. For example, a difference of 0.01°C. is near the limit of error with a gas thermometer, but it can be determined with considerable precision by many other thermometric devices. Nevertheless, it should be kept in mind that it cannot be proved that such useful devices correctly denote what they are assumed to represent except by comparison with the thermodynamic scale. It is hoped that this presentation of the above proposal will initiate wide discussion leading to appropriate action for its general adoption.

To summarize: The permanent adoption of the best value of the ice point, $T_{0^\circ\text{C.}}$, on the absolute temperature scale would:

(1) Permit an increase in the accuracy with which temperatures may be fixed on the thermodynamic scale.

(2) Eliminate confusion which results from lack of agreement as to the 'best value' of $T_{0^\circ\text{C.}}$ and

which would still result if there were occasional changes in a generally adopted 'best value'.

(3) Not in itself necessitate any changes in published thermodynamic data.

In order to emphasize the existing status of temperature scales, we will present the following account of the scientific method which will be entitled:

A Parable of Measures to Improve Weights

An early scientist, who deserves much credit, desired a standard of weight. He selected two convenient stones. The lighter stone was very smooth, hard and dense, and gave every indication of durability; the heavier stone was definitely of lower quality.

Now the accumulation of information available to this scientist being much less than that of the present, he failed to see the matter with as much clarity as might reasonably be expected of his current successors. His solution of the problem was to state that the heavier stone weighed 100 convenient units more than the lighter standard, which was taken as the zero of weight.

This system served very well for a time, but presently weights below zero were found to be necessary and the tradesmen scarcely knew whether they were buying or selling when the customers asked for 50 units of bread and minus 10 units of cheese.

A temporary respite from this difficulty was obtained in the following manner. A practical scientist decided to search for the lightest stone to be had. The search took him far and wide and, having failed to see nothing, he returned with a somewhat lighter standard for the new zero of weight. As a heavier standard he decided to use the weight of man, and the difference between the two standards was again defined as a certain number of units.

The new choice of the heavier weight was not a very fortunate one and it was soon decided to return to the former standards, but nevertheless the main feature of the plan was retained by making an approximate comparison of the two scales and defining a new unit. There has always been a diversity of opinion as to the desirability of this new unit; some called it more convenient and others called it less convenient, so we will refer to it as the more-or-less convenient unit. Thus 5 convenient units were found to equal 9 more-or-less convenient units and the old standards came out 32 and 212 more-or-less convenient units, respectively, on the new scale, while the new zero of weight was no standard at all. This scheme was of some temporary help to the tradesmen; but it

was not long before someone found weights below zero again and the whole more-or-less system became unpopular among scientists although it is still used by a few practical groups.

It was all very confusing and the difficulties were of an astonishing variety, but we must leave to the imaginations of our readers the trials of the early scientists who tried to develop such concepts as mass, gravitation, and the laws of dynamics with a system including negative weights.

Eventually it became apparent that weight had an absolute value and the standards were themselves determined in terms of convenient units. The lighter stone was found to weigh about 273 convenient units, but as always, there were experimental errors, and various contemporaries used values ranging from 270 to 276.

In due time the atomic theory was developed, and many years later the absolute weights of atoms were determined. For example, the deuterium atom was found to weigh 3.32×10^{-24} convenient units; however, in accordance with an international agreement this result was recorded as $-272.999,999,999,999,999,999,999,68 \pm 3.0$ convenient units.

The principal difficulty in the system was that the ratio of the weights was obtained by adjusting their positions on a supporting beam and fulcrum and using the relation

$$W_0 = \frac{100}{(W_1/W_0) - 1} \quad (1')$$

The percentage error of W_1/W_0 was unfortunately multiplied by 3.73 in obtaining W_0 . The limiting sensitivity of the balance was only one convenient unit of weight and one hesitates to contemplate the state of affairs if the standard stones had been 273 and 274 convenient units respectively. The experimenters would have obtained values of W_0 ranging from 137 to ∞ .

Now it so happened that the pedestal on which the heavier standard was kept was not very resistant to acid fumes from the laboratory and it became weakened almost to the point of collapse.

Moreover, it was observed that the standard itself had acquired some tarnish. Some say that this was hastened by workers with the small weights, who purposely heated some vitriol because they had tired of being on the negative end of things, but be that as it may, it was only the inevitable that happened when the standard was finally removed from its primary status.

In order to preserve the units in general use it was decided to adopt only the unexcelled lighter stone as a standard of 273 convenient units and soon everyone wondered why they had done otherwise.

Explanatory Note. It has not been expedient to simulate more closely the actual historical sequences and facts in making a point that refers to a twentieth century situation. As a matter of fact, there was an excellent reason for two easily obtainable fixed points in the early days of thermometry.

In 1654, Grand Duke Ferdinand II of Tuscany had bulb and stem thermometers calibrated in thousandth parts of the bulb volume. This very sensible approach to the problem, which required only one fixed point, was discarded later only because the expansion of various liquids did not yield identical results. This led to two fixed points

with the scale interval divided into a certain number of divisions and brought various thermometers into somewhat better yet crude agreement.

In 1701 Newton proposed the interval between the ice point and the none too uniform temperature of the human body as a scale of 12 degrees, and in 1714 Fahrenheit substituted the ammonium chloride - ice eutectic temperature for the ice point to avoid negative temperatures; but unfortunately the stage had not been set sufficiently so that he could see the ultimate goal. Later, Fahrenheit investigated and adopted the present fixed points. The centigrade scale was not proposed until 1742, when Celsius suggested it in reverse form.

The discovery and investigation of numerous gases took place in the eighteenth and nineteenth centuries. If this kind of investigation had not been delayed for so long, the first thermometer, based on the expansion of air and invented by Galileo in 1592, would have developed sooner into the modern gas thermometer, and it is difficult to imagine that the systems based on two fixed points would ever have originated.

Molecular Layers

THE foundation of the Pilgrim Trust series of lectures, of which the first was delivered by Dr. Irving Langmuir before the Royal Society in the theatre of the Royal Institution on December 8, 1938, was noted in NATURE of December 17 last. In this lecture, the subject-matter of which is printed *in extenso* in the *Proceedings of the Royal Society*, A, 170, 1 (1939), he gave a comprehensive account of his investigations on monolayers and multiple layers of complex organic molecules. These researches, initiated by him in 1917, and carried on by many workers, Langmuir himself always taking a leading part in advancing both theory and experimental technique, show no sign of ceasing to be a fertile field for investigation.

The orientation of organic molecules, with a water-soluble group at one end of a long hydrocarbon chain, at a water surface with the chains perpendicular, or nearly so, to the surface, now forms part of the subject-matter of many advanced text-books. The molecules orient themselves in this manner only if the hydrocarbon chains are sufficiently long for the lateral adhesion between

them to control the thermal motions of the molecules. If either the temperature is raised, or the length of the hydrocarbon chains is diminished, or the amount of adhesion between the adjacent molecules in the surface film decreases from some other change in constitution of the molecules, this simple orientation of the molecules may be destroyed. If the lateral adhesion is completely overcome, the molecules separate completely, the film becoming 'gaseous'. In the 'gaseous' state of the films, the molecules lie flat on the surface, provided there is sufficient space, and the relation between the area and the surface pressure is similar to that between volume and pressure in a gas.

There is an intermediate stage (the liquid-expanded films) between the condensed films, with molecules nearly upright, and the 'gaseous', in which they lie flat, which presented some very puzzling features until in 1933 Langmuir showed that they simulate very closely the behaviour of thin layers of a non-spreading paraffin oil, in which a small amount of a spreading substance such as a fatty acid is dissolved, thus forming a thin liquid layer of paraffin separated from the water by an

interface containing a gaseous film of fatty acid. In the liquid-expanded films, the hydrocarbon chains in the molecule appear to be in chaotic oscillation, similar to that of the molecules in a liquid except that the water-soluble end is anchored to the water. The greater part of the cohesion of such films is provided by the adhesion between the hydrocarbon chains, which persists just as in a liquid, in spite of the chaotic motions of these chains.

During the last four years, there have been important experimental developments. It has been shown that the properties of the monolayers of fatty acids may depend on the ions with which the end groups are associated, and that this may serve as a very delicate test for minute amounts of divalent or trivalent ions in the underlying solution; as little as one ion of aluminium for thirty atoms of stearic acid may alter noticeably the properties of the material skimmed up off a surface covered by a film, this quantity corresponding to a concentration of as little as one part in three thousand million of water. As a microchemical technique, the effects of ions on monolayers appear very promising, the amount of silver or gold dissolved when a piece of the pure metal is simply dipped into water sufficing to alter the viscosity of a monolayer of stearic acid appreciably, in a few minutes. This recalls the mysterious 'oligodynamic' poisonous action on living cells, caused by contact of these metals with water, and may be a first step to the understanding of this action.

Langmuir and Blodgett's multiple layers built up by repeated dipping of a solid plate into water covered by a monolayer under constant surface pressure are perhaps the most important recent development. These layers may be built up to several thousands of molecules thick, if dipping is continued long enough; their structure seems to be very similar to that of crystals of long-chain aliphatic substances with polar groups at one end of the molecule; that is, they have sheets of molecules parallel to the solid surface, with the molecules in successive sheets arranged with the polar groups pointing alternately towards, and away from, the solid. The layers with the polar groups directed to the solid are called 'endotropic'; those with these groups directed outwards, 'exotropic'. There are differences in the manner of deposition of these layers, according to the acidity of the water, and the salts contained in it; if the solution under the monolayer has a pH greater than about 9, layers are deposited only on entering the water (X films); on slightly less alkaline solutions the layers are deposited both on entering and on leaving the water (Y films). Multiple layers are not easily deposited unless there is some calcium

or barium in the solution, and they consist of a mixture of the free acid and the alkaline earth soap.

The free fatty acid may be dissolved out of the films by treatment with benzene, leaving the thickness of the film unchanged, but its refractive index is much diminished. It is possible to eliminate the reflection of light from glass, by covering it on both sides with a multiple film having a refractive index equal to the square root of that of the glass, and an optical thickness equal to one quarter wave-length; if this is done to any instrument having a glass front, the glass becomes invisible and the instrument can be used with light reflected at any angle, without disturbance from the 'shine' on the glass front.

There is some evidence that the molecules in the multiple layers can turn over. Drops of water on the surface can apparently, in some circumstances, cause the molecules to turn with their polar groups outwards. Dipping into solutions of such salts as thorium nitrate turns the exterior molecules over, and such 'conditioned' surfaces have remarkably interesting powers of adsorption; they are hydrophilic instead of hydrophobic, as the exterior 'endotropic' layers normally are. Adsorption of bile acids on such conditioned surfaces confers hydrophobic properties on the surfaces, but not of exactly the same kind as the properties of the original unconditioned outer layer. For some reason which is not yet clear, the surface of the unconditioned films, although hydrophobic, forms a finite angle of contact with oil and does not easily adsorb paraffin vapours. A conditioned layer on which a bile acid is adsorbed can in its turn adsorb hydrocarbon vapours, thus showing that adsorption even in simple cases depends on the detailed molecular architecture of the surface. Quite small stereochemical differences, for example that between cholesterol and epicholesterol, make a great difference between the power of penetration of digitonin into the outer layers of deposited films.

Monolayers of proteins are another field in which opportunities seem abundant. In solution, the proteins are compact molecules; on surfaces, they are unfolded to a thickness of probably one amino-acid. This may account for the denaturation of the protein, since the re-folding of a very complicated molecule, once it has been spread on a surface, is likely to be difficult. Some preliminary work on enzymes indicates some loss of activity when they are spread at a surface.

The lecture contains not only a survey of the whole of the work on molecular layers, but also it is full of most valuable new hints on technique, and suggests several new fields for further research.

Obituary Notices

Prof. H. M. Dawson, F.R.S.

HARRY MEDFORTH DAWSON, professor of physical chemistry in the University of Leeds since 1920, died on March 9 at the age of sixty-three years, after an illness which had disabled him during the whole of the current University session.

All his life, apart from three years' Continental training, was spent in Leeds, first at the Leeds Modern School and then in turn as student, demonstrator, lecturer and professor at the University of his home city. In the last year of his studenthip at Leeds he was engaged on research work with Prof. A. Smithells, and received the highest award then open to a student of science in his election to the 1851 Exhibition. There followed three years at Berlin, Leipzig and Gießen, which were all-important in bringing home to him the conviction that no work could henceforth make the first claim on his time and thought but that of research.

This inspiration came at a time when the atmosphere of the German universities was permeated by the research spirit to an extent then almost unknown in Great Britain, when brilliant young men were forming the research habit, and when new vistas were being opened out by theories and experimental investigations of the first importance. In the years just preceding, van't Hoff's original paper on "Osmotic Pressure and the Thermodynamic Deductions for Dilute Solutions," Arrhenius's "Theory of Isohydric Solutions" and Nernst's "Electromotive Activity of the Ions" had been published and Ostwald's text-books were presenting physical chemistry in a new light. Dawson and fellow-students from Great Britain (including Donnan), were brought under vivifying influences of personal contact and example and of the written word. On returning from Germany with a Ph.D. from the University of Gießen, he was appointed to a demonstratorship in physical chemistry in the department at Leeds from which he had gone as a student. From then onwards came a steady stream of papers on the mechanics of chemical change in solutions, embodying the results of experimental work carried out by himself and many senior students who received in succession the benefit of his training in research methods. A vast amount of matter was thus accumulated, and it was his reward that after many years a more generalised treatment of the results became possible. He was elected to the fellowship of the Royal Society in 1933, to the great gratification of his friends, who had come to fear that his devotion to work in the laboratory at Leeds rather than its effective exposition elsewhere might tell against that form of recognition. He had received the D.Sc. degree of Leeds many years before, in 1907.

Meanwhile, as primarily responsible for the lecturing and laboratory teaching in physical chemistry in the University, Dawson had developed the subject

not only for the students of pure chemistry but also for those of the various departments of applied chemistry and medicine, and in 1920 a professorship in physical chemistry was instituted, to which he was appointed. Throughout this time he had been an indefatigable worker, whose laboratory light was shining on most evenings and who seemed to regard the University vacation as a provision for minimizing interruption to research work. It was only during the last few years that warning of overstrain necessitated some diminution of effort.

Dawson's literary output was almost entirely that of his papers in the *Journal of the Chemical Society*, but he also contributed the section on general and physical chemistry to several numbers of the annual report of the Society and was one of the authors drawn upon by Abegg for his (German) treatise on chemistry.

Dawson's departmental preoccupations left him little time for the more general administrative work of the University, nor was it with him a primary interest, but he concerned himself with the award of scholarships, was for a considerable period a representative of Leeds on the Joint Matriculation Board of the Northern Universities, and at different times was dean of the Faculty of Science and the representative of Convocation on the Council. He will also be remembered as for many years the secretary of the Priestley Club, with a membership drawn from inside and outside the University, and notable for its friendly informality and the wide range of its scientific interests.

Prof. Dawson was fortunate in his family life. He married Miss Phillis Mary Barr, and she, with three sons and two daughters, survives him.

JOHN W. COBB.

Dawson's researches on solutions form a contribution to chemical science of great significance and importance. His earlier work was connected in the main with various aspects of chemical equilibria and more particularly with the formation of complex ions. Thus he was able, by means of distribution experiments, to establish the existence of the complex ion $(\text{Cu}_4\text{NH}_4)^{++}$ in ammoniacal copper sulphate solutions. The other group of compounds in which he was interested was the polyiodides. Here, having confirmed Jakowkin's conclusion of the existence of the tri-iodide in aqueous solutions, he extended the observation to organic solvents such as nitrobenzene, in which he showed that, under appropriate conditions, the higher polyiodides KI_3 , KI_4 , KI_5 exist in significant proportions.

Although this work was of considerable importance, Dawson's name will be particularly associated with the kinetic measurements which were so largely instrumental in the successful development of the modern theory of acids and bases. A commencement

was made in 1909, when, following Lapworth's classical experiments on the bromination and chlorination of acetone, it was shown that iodination is similar in that the chemical change the speed of which is measured is the conversion of the ketone into the enol form. This was followed by a study of the catalysis of the reaction by acids, which led in 1913 to the conclusion that both the ionized and unionized portions of an acid exert a catalytic effect.

The work was not resumed until some years after the Great War, but then followed a rapid succession of papers which resulted in the establishment of the multiple theory of catalysis. The reactions studied included the iodination of acetone, the hydrolysis of ethyl acetate, the iodination of mesityl oxide and the intramolecular transformation of phorone, all of which are catalysed by acids and bases. Dawson demonstrated that in these reactions it is necessary to attribute catalytic activity not only to hydron and the hydroxyl ion, but also to undissociated acid molecules and to acid anions, and in fact to any substance which can either receive or donate a proton, that is, to any substance which in the Brønsted-Lowry view is an acid or base. Dawson was not content until his multiple theory was proved up to the hilt, and to this end he subjected the very considerable amount of experimental material to an exhaustive and searching analysis. A more complete and convincing proof of a scientific theory has rarely been achieved.

An account of Dawson's work in this field would be incomplete without some mention of his contribution to our knowledge of the effect of catalytically inert salts on the strength of acids, the effect which Brønsted calls the secondary salt effect. By means of kinetic measurements he showed that the dissociation constant of an acid is markedly affected by the presence of such salts. The change in dissociation constant is represented by an equation of the same form as that to be anticipated by the application of the Debye-Hückel theory of strong electrolytes, but Dawson was at pains to emphasize that quantitatively the results are incompatible with this theory.

During the last few years, Dawson was engaged in a study of the kinetics of the hydrolysis of the halogenated acetates. He revealed the complex nature of these apparently simple processes, and by an extremely elegant method succeeded in disentangling the various reactions, and evaluating the corresponding coefficients.

R. WHYTELAW-GRAY.
G. F. SMITH.

Prof. S. P. L. Sørensen

SØREN PETER LAURITZ SØRENSEN, whose death, at the age of seventy-one years, was recently announced, was the son of a farmer, Hans Sørensen. He was born at Havrebjerg, Slagelse, on January 9, 1868.

Leaving the High School at Sorø in 1886, Sørensen proceeded to the University, where he gained the University Gold Medal in the years 1889 and 1895. Having taken the degree of master of science at the

University he soon found himself consulting chemist to the Danish Naval Department's Laboratory. As the result of his work on cobalt oxalates he obtained the degree of doctor of philosophy in 1899. From what we know of Sørensen's early activities it is scarcely surprising to find that at the age of thirty-three years he was appointed director of the world-famous Carlsberg Laboratory in Copenhagen, a position he held until his lamented death in the present year. With the passing of Sørensen, the Carlsberg Laboratory has lost another of its distinguished line of workers. Who will forget Emil Oh. Hansen, its first director, whose work on the cultivation of single-cell yeast created such a drastic change in Continental methods of brewing; Johannes Schmidt, the eminent biologist, or Sørensen's immediate predecessor, Joh. Kjeldahl, whose name is familiar to everyone who has ever made a determination of nitrogen?

Although primarily interested in fermentation problems, Sørensen's classic work on hydrogen ion concentration will remain as a permanent monument among those who know little of his other work. The term 'pH' has become so much a part of scientific literature and its influence so important a factor in considering biological problems that one wonders how theories of acidity and alkalinity were ever formulated without a knowledge of Sørensen's fundamental conceptions. So far has the influence of this famous theory spread that to-day one hears golfers talking of the pH of their 'greens' and gardeners of their lawns.

Less spectacular perhaps, but equally important in the region of fermentation, was Sørensen's work on the synthesis of amino-acids, his studies on the proteins and his detailed and comprehensive investigation of enzyme behaviour. This latter study led him to perfect the well-known 'formol-titration' method for the estimation of certain types of nitrogen. Although Sørensen published from time to time in the *Journal of the Institute of Brewing*, most of his original work appeared in the *Biochemische Zeitschrift* and the *Comptes rendus* of the Carlsberg Laboratory.

Sørensen was an early member of the Royal Danish Academy of Science and later its chairman. He enjoyed honorary membership of a very large number of scientific bodies, including institutions in Uppsala, Stockholm, London, Paris, Boston (U.S.A.) and in other countries. He held three Danish Orders in addition to the Chevalier de la légion d'honneur and other foreign decorations.

I cherish the recollection of a happy meeting with this remarkable man in his laboratory in Copenhagen. He was kindly, courteous, ever willing to listen to those who had not his fund of knowledge and always ready and glad to impart something from his vast store of learning. Sørensen was happy in his domestic life and his second wife, Margrethe Høyrup, a woman of considerable intellectual ability, collaborated with him in much of his later published work.

Sørensen's reputation is assured, and his name will go down among the most illustrious of the past. With his going the world of science loses one of its great men and Denmark one of her most worthy sons.

A. J. CURTIN COBBIN.

Prof. A. M. Hocart

WE regret to record the death of Prof. A. M. Hocart, professor of social anthropology in the University of Cairo, which took place on March 9 at the age of fifty-five years.

Arthur Maurice Hocart was born in Guernsey, and entered Exeter College, Oxford, as an open scholar in classics in 1902. On taking his degree he was elected to a senior studentship of Exeter College and afterwards of Jesus College, where he devoted himself to the study of anthropology. He afterwards joined an anthropological expedition to the Solomon Islands organized by the late Dr. W. H. R. Rivers, with whom he contracted a close friendship, and by whom the subsequent trend of his studies was strongly influenced. After a period of travel and research in Melanesia, Hocart accepted a Government post as inspector of schools on the appointment of Sir Everard im Thurn, then Governor of the Western Pacific, and during the residence in Fiji entailed by his duties he engaged in anthropological observation among the Fijians, collecting much material on the traditions, social organization and beliefs of the people, which he utilized to good purpose in his later writings. Its influence is especially apparent in his book on "Kingship" (1927).

In 1921, Hocart was appointed director of the Archaeological Department in the island of Ceylon, and the influence of his energy, scholarship and enthusiasm for his subject soon made itself apparent in an increased and extended activity in his department's survey of the ancient monumental remains of the island, as well as in the standard, character and range of its publications.

Hocart's health, never robust, and showing traces of the effects of his residence in the Pacific, led to the resignation of his post in Ceylon, and in 1929 he returned to England, where for a period he acted as librarian of the Royal Anthropological Institute. In 1934 he succeeded Dr. E. E. Evans-Pritchard in the chair in the University of Cairo, which he occupied until his death.

Hocart's work in Melanesia had provided him with a wealth of ethnographical material which he was engaged in digesting over a considerable period of years and of which he published selections from time to time in the *Journal of the Royal Anthropological Institute* and other publications of a more or less technical character. His books were of a more general and theoretical outlook. In "The Progress of Man" (1933) he made a general survey of the subject-matter of anthropological science. It is both sound and original, while salted with a humour which at times was biting. In 1936 his "Kings and Councillors" was published in Cairo.

Hocart in outlook and method was a diffusionist in the sense that he followed Rivers in making use of precise cultural analysis in tracing the history of cultural and ethnic distributions; but in applying this method to general anthropological problems, his meticulous sense of scholarship deprecated any loose generalization based upon vague analogy, avoiding it in his own work and criticizing it sharply in others.

Sir Basil Thomson, K.C.B.

THE sudden death of Sir Basil Thomson, formerly assistant commissioner of the Metropolitan Police and director of intelligence at Scotland Yard, which took place on March 26 at the age of seventy-eight years, brings to a close a career no less remarkable for the versatility it displayed than for its actual achievement. Its interest for the anthropologist lies in the fact that as a colonial officer, Thomson was an outstanding example, among members of the old school of administrators, of those who, while without special training in anthropology, attained efficiency in their methods of administration in dealing with native affairs by acquiring and applying a sympathetic knowledge and understanding of native institutions and ways of thought.

Basil Home Thomson, son of William Thomson, Archbishop of York, was born on April 21, 1861, and educated at Eton and New College, Oxford. He entered the Civil Service and served for ten years in Fiji, Tonga and New Guinea. In 1900, after he had retired from the Colonial Service for some years, he returned for a period to the Pacific, being seconded under the Colonial Office as a special commissioner to negotiate treaties with two of the native Governments.

Among Thomson's numerous works, the writings of his earlier years are of more than passing interest to the anthropologist. He was an accurate and systematic observer, with insight into the characters and ways of thought of the peoples with whom he had to deal. His books, describing conditions which have now passed away, have a permanent value as records. In "The Diversions of a Prime Minister" (1894) he describes with no little humour the remarkable condition of affairs which he encountered as prime minister of Tonga, when he succeeded the notorious Shirley Baker. This was followed by "Discovery of the Solomon Islands" (1901) and "Savage Island" (1902), and "Fiji and the Fijians" (1908), now a standard book, which commands a rising price in the market. He also contributed papers to the *Journal of the Anthropological Institute*, of which one is a careful description of the remarkable stone trilithons of Tongatabu.

WE regret to announce the following deaths:

Sir William Butler, president of the Institute of Brewing in 1906, who was connected with the School of Brewing in the University of Birmingham for many years, on April 5, aged seventy-two years.

Prof. J. W. Edington, professor of bacteriology in the University of Sheffield, known for his researches on diphtheria, on April 8, aged fifty-four years.

Prof. W. E. Ford, professor of mineralogy in Yale University since 1920, on March 23, aged sixty-one years.

Prof. G. Hellmann, professor of meteorology in the University of Berlin.

Dr. W. H. Park, emeritus director of the Bureau of Laboratories of the New York City Health Department, known for his work on combating diphtheria and other diseases, on April 5, aged seventy-five years.

News and Views

Dr. Aleš Hrdlička

ON March 29, Dr. Aleš Hrdlička, curator of the Department of Physical Anthropology of the U.S. National Museum, Washington, D.C., and the founder of the study of physical anthropology in America, celebrated his seventieth birthday. The occasion has been marked by a gathering of the American Association of Physical Anthropologists at Washington during April 4-5, and a commemorative volume is being prepared, to which the principal anthropologists of the world have contributed. Aleš Hrdlička was born in Bohemia on March 29, 1869, and graduated in medicine in New York. In 1903 he was invited to become assistant curator in the U.S. National Museum to organize a department of physical anthropology, of which he became curator in 1910. Under his direction, a collection has been built up, which is now the largest in the world, including more than 16,000 skulls, human and sub-human, from all parts of the world and of all ages. As an authority on the descent and racial affinities of man, Dr. Hrdlička's judgment is universally received as authoritative. Bold in theoretical argument, his views are invariably characterized by an intensely conservative regard for the precise limitations of the evidence in question. He is best known, perhaps, as the foremost authority on the occurrence of early man in America and the Asiatic origin of the American Indian race, of which he has found the ancestral stock in the primitive strata of Siberian peoples. For more than a decade Dr. Hrdlička has engaged in expeditions to the far north in each summer to investigate the evidence of the migrations of the Eskimo and their predecessors into the American continent. He will submit the results of his research to the Royal Anthropological Institute at a meeting to be held in London on April 25.

Herschel's Researches on the Structure of the Heavens

To celebrate the bicentenary of the birth of Sir William Herschel, the first president of the Royal Astronomical Society, a conversation was held in the rooms of the Society on November 16. Sir Arthur Eddington delivered the lecture with the above title twice during the evening (*Occasional Notes, Roy. Astro. Soc.*, No. 3, January 1939). He pointed out at the beginning that in about thirty years the dimensions of the galactic system have been enlarged tenfold and the number of stars is now estimated to be 100,000 millions. It is remarkable that the picture of the universe which has resulted from modern research is very like the universe described by Sir William Herschel. His greatest enterprise was the systematic survey of the heavens, in the course of which he catalogued 2,500 nebulae and 800 double stars, and in all his research there was a definite plan to find out something about the structure of the universe. It seems remarkable that most of his observational

work on the general distribution of stars and nebulae was done with a reflector of only 19 inches aperture; the famous telescope of 4 ft. aperture was not a success and was not used very much. It is surprising that Herschel's speculations did not lead him astray more often. As one example, he assumed all stars to be of the same brightness, so that first magnitude stars were nearer than second magnitude stars, and so on. Actually, as we know to-day, apparent magnitude is a poor guide to distance. At the end of the lecture, Sir Arthur said that it is impossible for us to communicate with nebulae and receive a reply if they are more than 950 million light-years from us, owing to the speed of recession of the nebulae. It is expected that the 200-in. telescope will reach nebulae 1,000 million light years from us, so it is possible that we shall see galaxies with which it is impossible to communicate and receive a reply.

Study of Edmund Burke's Financial Integrity

DIXON WECOTER has recently investigated with the help of new material the vexed question of Edmund Burke's financial integrity, and the extent to which he was involved in the discreditable ventures of his brother Richard and his kinsman William Burke ("Edmund Burke and His Kinsmen", by Dixon Wecoter. University of Colorado Studies, No. 1, 1, Feb. 1939). Since he vehemently defended their actions at all times and denounced their adversaries and critics in unbridled terms, it is not surprising that Edmund Burke himself came under suspicion of conniving with them. Nevertheless, the author concludes from all the evidence now available that Burke honestly believed them to be upright in their financial transactions, however unfortunate their outcome, and there is no doubt that in his office as paymaster Burke reduced the nation's finances to order at considerable cost to himself. In any event he was always vague as to his own income and expenditure, and it is difficult to imagine him following the tortuous ways of his kinsmen with any care. Burke's passionate championship of those shady characters, while not historically important, shows how completely his judgment was blinded by sentiment. Of more material consequence is the parallel traced by the author between the changing course of William Burke's fortunes in India and Edmund Burke's change of attitude towards the East India Company, leading to the impeachment of Warren Hastings. It is not suggested that this connexion was perceived by Burke himself, whose advocacy the author believes to have been at all times passionately sincere. Of all men a great orator is perhaps the least likely to be aware of the less reputable sources of his interest. He was temperamentally unfitted to judge objectively either friends or adversaries, and this study admirably illustrates the importance of temperamental make-up in life.

Carnegie Trust for the Universities of Scotland

THE recently published report for 1937-38 of the Carnegie Trust for the Universities of Scotland includes detailed reviews by Sir William Bragg and other eminent authorities of the operation during the quinquennium 1933-38 of the Trust's scheme for the endowment of post-graduate study and research. The scheme involved last year the expenditure of £19,000—about 15 per cent of the Trust's total disbursements, of which £51,000 went in grants to universities and colleges and £54,000 in assisting needy students to pay their class fees. The reports indicate that its results amply justified the research scheme, being fully up to the standard set in previous years. A noteworthy feature of its operation is the large number of the recipients of awards of fellowships and scholarships who are appointed to responsible positions on the staffs of universities and other institutions for teaching and research. This, remarks Prof. J. T. Wilson, emeritus professor of the University of Cambridge, in his report on the biological and medical section of the scheme, is in keeping with one of its outstanding functions: the establishment and reinforcement of a trained corps of scientific investigators constantly available for recruitment to the service of the community in its higher schools of scientific learning. As regards expenditure by the Trust on payment of class fees, a number of the beneficiaries afterwards refund the amounts thus paid on their behalf. Such voluntary refunds fluctuate between 2½ and 5 per cent of the total amounts advanced by the Trust.

Chemical Society: Anniversary Meetings

THE anniversary meetings of the Chemical Society were held in London on March 29-31. On March 29, the Rutherford Memorial Lecture entitled "Lord Rutherford: His Life and Influence on Chemistry" was given by Sir Henry Tizard, at the Royal Institution (see p. 651). In the evening, fellows of the Society and their guests, numbering in all about four hundred, were entertained by the chairman and directors of Imperial Chemical Industries, Ltd., at Imperial Chemical House. On March 30, there were visits in the morning to Bedford College for Women and to the Wellcome Research Institution, where conducted parties were taken over the Museum of Medical Science and the Historical Medical Museum and the Chemical and Physiological Research Laboratories. In the afternoon, the business part of the annual general meeting was held at Burlington House, and the presentation of the Longstaff Medal for 1939 was made to Prof. I. M. Heilbron and of the Harrison Memorial Prize for 1938 to Mr. Alexander King. Prof. F. G. Donnan then delivered his presidential address entitled "The Role of Osmotic Pressure in the Development of Chemical and Biochemical Science". The anniversary dinner was held the same evening at Grosvenor House, the number present being 270. Prof. F. G. Donnan occupied the chair, the principal guest of the evening being Viscount Samuel. On March 31, there were visits to the British Drug Houses, Ltd., and also to

the Central Laboratories of the Shell Marketing Co., Ltd., at Fulham. In the afternoon, there were visits to the Research and Development Department of the Distillers Company at Great Burgh, Epsom, and to the Laboratories of the Research Association of British Paint, Colour and Varnish Manufacturers at Teddington. The following have been elected officers of the Society: *President*, Sir Robert Robinson; *Treasurer*, F. P. Durin; *Secretary*, Prof. G. M. Bennett.

Population and Fertility

A PAMPHLET of 101 pages, entitled "Population and Fertility", has been issued by the Population Investigation Committee, 69 Eccleston Square, London, S.W.1 (price 3s.). It has been prepared for the Committee by Mr. D. V. Glass and Dr. C. P. Blacker. The Population Investigation Committee was formed to examine the trends of population in Great Britain and the Dominions and to investigate the causes of these trends with special reference to the fall in the birth-rate. Many causes for this decline have been suggested; but multiple causes are at work affecting different occupations and different parts of the country in many complicated ways, so that effective counter-measures will not be easy to find. The problem is to find out how and why fertility has declined. For analysis of the first part, statistics of birth-rates and fertility-rates are given for England and Wales, the Dominions, U.S.A., Sweden, Germany, France, Italy, Ukraine and Japan. The table of net reproduction-rates for thirteen countries shows that only five of these populations are now replacing themselves. Interesting details are given regarding the history of the census in Great Britain and the recent Population (Statistics) Bill. It is pointed out that the latter is inadequate for a full fertility census, and certain additional questions are suggested for the next census. In the last two chapters, the limitations of vital registration statistics in analysing the psychological motives of childlessness are discussed and possible counter-measures are considered.

Royal Aeronautical Society

THE Royal Aeronautical Society has now moved into new headquarters at 4 Hamilton Place, London, W.1. This is the first time during its seventy-three years of existence that the Society has had its own building. The Society's new home is a four-story building which will allow for expanding activities for some years to come. The library will be one of the finest and best equipped aeronautical libraries in the world. There will be, in addition, a reading and other rooms for members and special committee rooms for the use of the many aeronautical committees which are now sitting. It is hoped to make the building the centre of aeronautical engineering and scientific activity in Great Britain. Dr. A. H. R. Fiddan, president of the Society, announced at the recent annual general meeting that to meet the increasing work of the Society and the upkeep of its new premises a fund of £100,000 is being aimed at, to which more

than £80,000 has already been promised. In July 1940 the Society will hold an International Aeronautical Conference at Stratford-on-Avon. The active support of the Air Ministry and the Society of British Aircraft Constructors in Great Britain and of the leading authorities in the United States, France, Germany and Italy has been promised.

New Air Speed Record

It is reported that Herr Dieterle, flying a German Heinkel aeroplane fitted with a Mercedes-Benz engine, has set up a new speed record of 483.8 miles an hour over a three kilometre course. This does not rank as an official record until it has been examined and homologated by the Fédération Aéronautique Internationale; but there is no reason to doubt that this formal recognition will be given in due course. This has beaten three world records at the same time: the 3 km. of 380 m.p.h. held by Wurster (Germany), the 100 km. of 394 m.p.h. held by Udet (Germany), and the absolute speed record of 440.7 m.p.h. held by Agello (Italy). No certain details of the aircraft are known, but it was probably developed from the Heinkel He.112.U used by Udet for the 100 km. record in June 1938. Statements that have appeared in non-technical reports that the machine was a single seater fighter fitted with an engine of 1,175 horse-power are obviously misleading. Any machine of this class must have been very thoroughly 'cleaned up' in design for such speeds, and even with such alterations the engine must have been both speeded and boosted up to a power of well over 2,000 b.h.p.

Deaf-Aids in Theatres

An interesting development in deaf-aids has been recently demonstrated in Wyndham's Theatre, London, and is being installed in a number of cinemas. Hitherto a deaf person in a cinema could frequently be supplied with a listening telephone, operated by an amplifier following a microphone located near the loud speakers behind the screen, or from the actual sound-film amplifying equipment itself, but the user was necessarily tied to his seat by the connecting wire. In the 'Telesonic system', made practicable by Messrs. Multitone Electric, an efficient type of deaf-aid is operated by a pick-up coil, in which are induced currents from an energized cable hung round the auditorium or placed under the carpet. In a theatre, a microphone in the footlights operates a specially corrected amplifier of about ten watts capacity, the output of which is fed into the magnetizing cable by a specially designed transformer. On demonstration, the device worked well and adequate audition was obtained, with freedom to move over the whole area of the seats, or even some distance outside this area. The fundamental idea of direct speech or music induction without a radio carrier is not, of course, new, but it is understood that the main feature of the invention is the disposition of magnetizing coils such that cross-talk between adjacent theatres or cinemas using the system is obviated. The normal

deaf-aids manufactured by the Multitone Company are now arranged to operate with the 'Telesonic system' in theatres.

Visual Aids in American Schools

A RECENT survey of the employment of visual aids in schools representing two thirds of the total enrolment in public elementary and secondary schools in the United States indicated that the use of (1) pictorial materials, (2) objects, specimens and models, and (3) visual aids which require mechanical equipment, was habitual in the instruction of (1) 61 per cent, (2) 52 per cent and (3) 27 per cent, respectively, of the pupils included in the survey, and that about 10,000 projectors were owned by the schools. A large percentage of the school systems not reporting were in rural districts, and the data concern, therefore, conditions in urban communities primarily. An interpretative study of these data has been published by the Office of Education ("School Use of Visual Aids". Supt. of Documents, Washington, D.C. 10 cents). There is very widespread interest in the subject (which formed the theme of thirty-seven research studies in 1936-37), and there is general agreement that the motion-picture has great potential educational value and but little apprehension that it may prove, as forecast by Georges Duhamel (in "Défense des Lettres") and others, to be one of applied science's Greek gifts to culture. Among the further developments recommended in the light of this survey are the production of high-grade educational films, a nation-wide distribution system, training courses in the technique of teaching with motion pictures and other visual aids and improvement of the 16 mm. projector so as to make it easier for amateurs to operate.

Antiquity

AN editorial note in *Antiquity* of March, 1939, directs attention to an important development in the study of European prehistoric chronology. E. H. de Geer, it is stated, has succeeded in equating the growth-rings of trees from the ancient mound of Rakenhangen in the Romerike district of Norway with those of a giant Californian sequoia on one hand, and with clay varves from Angermanland in North Sweden on the other. The tree trunks examined were preserved when a shaft was sunk to the base of the mound in 1868. The investigation points to A.D. 931 as the date of the cutting of the trees and the erection of the mound. As the editor of *Antiquity* points out, the acceptance of the full implication of this important discovery must await further critical examination; while the application of dendrology to European chronology is not without its peculiar difficulties. The March issue of this enterprising periodical well maintains its high standard of interest, in part owing to the inclusion of Prof. V. Gordon Childe's lecture on the relations of India to the West before the time of Darius, which originally was delivered before the Warburg Institute on October 10, 1938, and Dr. R. E. Mortimer Wheeler's report on his excavations in Brittany, to which

reference has already been made in *NATURE* (see *NATURE* of March 4, p. 386). The report is fully illustrated and accompanied by plans. Mr. James Hornell draws on his world-wide knowledge of the construction of various forms of boat to trace the plank-built boat to its origin. Among the interesting shorter notes which are always a feature of the contents, mention should be made on this occasion of a valuable suggestion from Mr. Stanley Casson, urging the prosecution of submarine research in the coastal waters of Greece. He points out that not only are the sea routes of antiquity well known, but recent discoveries of statuary, especially bronzes of the best period of classical art, support the argument that cargoes of artistic loot on the way to Rome may have been lost with some frequency.

Design of Electric Power Stations

AN important paper by F. W. Lawton was read to the Institution of Electrical Engineers on March 9 dealing with the design of Hams Hall power station at Birmingham, designed twelve years ago, and with a new Hams Hall power station *B* which will be constructed shortly for the same purpose and on a neighbouring site. The author stresses the point that from the time when the calculations for a proposed power station are made until it is completed and running on a commercial load, several years may have elapsed and great changes may have occurred. For example, the average price of the coal used in the furnaces is now 17s. per ton as against 9s. 6d. in 1925. In designing the new station it was reasonable to consider which features of the old station should be repeated and which rejected in the new station built twelve years afterwards. During this time coal prices have increased, high voltages have become normal and the progress made in metallurgy has made much higher steam temperatures feasible. All these changes call for modification in the designs if the best efficiency and economy are to be obtained. As regards the general lay-out, the simplicity and uniformity of the existing station will be repeated. There is a single row of boilers parallel to a single end-on row of turbo alternators. Electrostatic flue-gas cleaning plant will be retained. The absence of architectural adornment of the new buildings will be more rigorously enforced. Air raid precautions insist that there must be no roof lights or external windows to basements. For economic reasons the superstructure will be made of ferro-concrete instead of structural steel. Turbo-alternators of 50,000 kw. capacity each will again be used in the new station, but they will generate at 33,000 volts instead of at 11,000 volts as in the present station. A true understanding of what is real economy is obscured by the ever-changing technology of power production, by the difficulties of accurately forecasting operating conditions many years ahead, and by reactions of local trade developments.

Research at the Kodak Laboratories

THIRTY-NINE papers are covered in the recently published "Abridged Scientific Publications from Kodak Research Laboratories" (vol. 19. Pp. viii+

288. Rochester, New York: Eastman Kodak Co.). The wide variety of subjects studied at the Kodak Laboratories is well illustrated. Most of the papers have some obvious connexion with photographic manufacture or technique. Among these may be mentioned specially four papers dealing with the measurement of photographic density. This has never yet been standardized and, though for most technical purposes 'density' is sufficiently well understood to permit useful application of measurement to laboratory testing and works control, yet for precise comparison of results obtained on different instruments of slightly different design, there is need for much further progress. Perhaps the new information may be useful in achieving this. There are, however, several papers which are devoted to subjects which are outside the photographic field altogether, and here we may cite a group of papers by Dr. K. C. D. Hickman and colleagues dealing with fractional distillation of phlegmatic liquids. The work has resulted in development of much improved apparatus for distillation of vitamins. As with previous volumes, each paper is presented without drastic shortening, so that to those who are not able to turn to the full papers in their original journals the volume is of exceptional value.

Scottish Wild-Life Preservation

THE Council of the Zoological Society of Scotland recently set up a Scottish Nature Reserve Committee, on which various public bodies are represented, for the purpose of promoting the preservation of Scottish wild-life. The Committee wishes to obtain full and accurate information regarding the existence, numbers, increase or decrease, and generally the most complete statistics, of native species in different parts of the country. The Committee believes that helpful information of this kind could be furnished by local natural history societies and other associations as well as by landowners, gamekeepers and others, and, therefore, it desires the co-operation of anyone who could furnish such information and who would collaborate with the Committee in the work which it hopes to do. Another aspect of the work which the Committee might usefully undertake would be the mapping out of areas in Scotland which might be suitable for Nature reserves or sanctuaries. Anyone who possesses local knowledge of the suitability of land for such a purpose could greatly assist the Committee by communicating such information to it. Communications should be sent to the Director-Secretary, the Zoological Society of Scotland, Zoological Park, Edinburgh, 12.

Biology and Social Studies

Fact, now successfully at the end of two years' activity, which produces, in its own phrase, "A monograph a month", has just brought out another scientific number bearing the title "Biology and Man: Past and Future" by Prof. Marcel Prenant of the Sorbonne. This for the most part consists of an interesting and well-written summary of the main trends in the history of biology in relation to

contemporary social and economic backgrounds. This is seconded by an able essay from Dr. H. J. Muller, who is well known as a geneticist, now of Edinburgh, entitled "The Dominance of Economics over Eugenics" in which the relationship of social systems to human inheritance, and the true value of eugenic hopes, are discussed. He propounds the question whether the present social systems of western Europe do not involve a selection of socially inferior rather than of socially superior human material. These contributions should be of interest not only to all biologists, but also to much wider circles. *Fact* is edited by Mr. R. W. Postgate; Mr. H. G. Wells has recently joined its editorial board.

Standards on Electronics and Radio Receivers

THE Institute of Radio Engineers (330 West 42nd Street, New York) was founded in 1912 to advance the theory and practice of radio and allied branches of engineering and to maintain a high professional standard amongst its members. Although dominantly in the United States of America, the Institute membership of more than 5,000 persons is distributed throughout the world. The *Proceedings*, published since 1913, is issued monthly and contains contributions from leading workers in the theoretical and practical fields of radio communication. It has co-operated with many other bodies in the establishment of standards. It has published many reports dealing with the definitions of terms, letter and graphical symbols, and methods of testing and rating equipment. Now it has issued "Standards on Electronics, 1938" and "Standards on Radio Receivers, 1938" (price 50 cents each). The committees which drew up the pamphlets are to be congratulated on the thorough way they have done their work. Every radio engineer and teacher of technical electricity should have a copy of these pamphlets, for they are most useful for reference.

Interplanetary Travel

WE have received vol. 5, No. 1 of the *Journal of the British Interplanetary Society*, a body "founded for the stimulation of public interest in the possibility of interplanetary travel, the dissemination of knowledge concerning the problems which the epoch-making [*sic*] achievement of an extra-terrestrial voyage involves, and the conducting of practical research in connection with such problems". This number of the *Journal* contains designs for a "space ship" intended to perform a voyage to the moon and back. While we may invite the charge of obstructionism if we dismiss the whole affair as a wild-cat speculation, it is necessary for us to remark that, while the ratio of research results accomplished to speculative theorizing is so low, little confidence can be placed in the deliberations of the British Interplanetary Society.

The Midwifery Service

THE annual report of the Central Midwives Board for the year ended March 31, 1938, has been issued (London: H.M. Stationery Office. 4d. net). At the

end of the year, there were 67,089 women on the midwives roll, a net increase of 2,043 on the total for the previous year, but only a little more than a quarter of the total number of those on the roll are engaged in the practice of their profession. The number of candidates entering for the examination was 4,420, the highest number ever recorded, of whom three quarters were successful. The report sets out the arrangements made by the Board for the approval of institutions, lecturers and teachers under the rules, of which a detailed explanation is given.

Science Abstracts

NEITHER science nor industry is standing still and to anyone who wishes to keep abreast of the advances made, the two sections of *Science Abstracts*—Physics and Electrical Engineering—are of great service. The two index numbers published in the last week of February completed the volumes for 1938. The Physics Section contains 5,081 abstracts from about half that number of publications, the average number of the abstracts being about 4.3 per page. The index of subjects covers 189 pages, that of apparatus 22, and the author index 65 pages. The Electrical Engineering Section has 3,622 abstracts, about 4.6 to a page, with a subject index of 59 pages and an author index of 31 pages. The Physics volume is thus about 10 per cent less than, and the Electrical Engineering volume about 3 per cent larger than, the volume for 1937.

British Empire Cancer Campaign

THE seventieth quarterly meeting of the Grand Council of the British Empire Cancer Campaign was held on April 3. The following grants were approved, making a total to date for the year 1939 of more than £48,000: £1,000 to the North of England Branch of the Campaign for the continuation of the special short-wave investigations being carried out under the direction of Dr. F. Dickens; and £160 to Mr. E. Nevill Willmer, working at the University of Cambridge. The Council received a report regarding the joint discussions which had taken place between representatives of the Campaign, the Medical Research Council and the National Radium Commission on the subject of the installation of a cyclotron in Great Britain primarily for medical and biological investigations as affecting the cancer problem. The three bodies have now jointly agreed to refer this matter for further consideration to the Radiology Committee. A further sum of approximately £6,500 is to be allocated to meet the expenses to be incurred during the second year's working of the scheme of the Clinical Cancer Research Committee. This scheme covers an inquiry into all fresh cases of cancer in the London area, and during the first two years the results of investigations into approximately 34,000 cases will have been placed at the disposal of the Committee. Dr. J. M. Woodburn Morison has been invited to become the representative of the Campaign on the Scientific Advisory Committee of the newly amalgamated Radium Institute and Mount Vernon Hospital.

Travelling Fellowships in Medicine

THE Medical Research Council invites applications for six Rockefeller Medical Fellowships for the academic year 1939-40. These are provided from a fund with which the Council has been entrusted by the Rockefeller Foundation of New York. They are intended for British graduates who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science, and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad, before taking up positions for higher teaching or research in the United Kingdom. The stipend will ordinarily be at the rate of £360 per annum for a single Fellow, and of £480 per annum for a married Fellow. Travelling expenses and some other allowances will be paid in addition. The Council also invite applications for four Dorothy Temple Cross Research Fellowships in Tuberculosis, which are awarded from a special endowment of which the Council is the trustee. The object of these Fellowships, as defined in the Trust deed, is to give special opportunities for study or research to suitably qualified British subjects of either sex "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms". The stipend will ordinarily be at the rate of £350 per annum for a single Fellow, and of £480 per annum for a married Fellow, with an allowance for travelling and incidental expenses. Further information can be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S.W.1.

International Foundry Congress

ARRANGEMENTS for the 1939 International Foundry Congress, to be held in London during June 12-17, are now almost complete. The official opening of the Congress by the Lord Mayor of London, Sir Frank Bowater, will take place on the morning of June 13, and afterwards Prof. W. L. Bragg will deliver the fourth Edward Williams Lecture entitled "The Atomic Pattern of Metals". Some forty papers will be presented to the Congress, and a joint meeting with the Iron and Steel Institute will be held on June 16. In addition to these technical sessions, at which all phases of ferrous and non-ferrous foundry practice and metallurgy will be discussed, eleven companies in London and the home counties have consented to open their works to Congress delegates, and the director of the National Physical Laboratory has offered to show a party round the metallurgical section of the Laboratory. The Government will give a reception on June 13, and other social functions include the annual banquet on June 14 and the reception to be given by Mr. W. B. Lake, president of the Congress, and Mrs. Lake on June 15. A tour of the principal foundry centres of Great Britain has been arranged to follow the Congress, and is divided into two sections: June 18-24 and June 25-30. Delegates may participate in either the first or both weeks of the tour, during which they will be able to inspect twenty-six of Britain's leading foundries.

Further particulars concerning the Congress and the tour are obtainable from the organizers, the Institute of British Foundrymen, St. John Street Chambers, Deansgate, Manchester, 3.

Announcements

THE Linnean Gold Medal, awarded annually by the Linnean Society of London "to an eminent biologist as an expression of the Society's estimate of his services to science", has been awarded to Prof. E. D. Merrill, professor of botany in Harvard University and supervisor of the Arnold Arboretum.

PROF. E. J. SALISBURY will deliver the Symons Memorial Lecture of the Royal Meteorological Society on April 19 at 7.30. The subject of Prof. Salisbury's lecture will be "Ecological Aspects of Meteorology".

PROF. WERNER KNOTHE, of Berlin, has been elected president of the Berlin Röntgen Society.

THE University of Bologna has awarded the Umberto Prize, given every five years for the best scientific work on orthopaedics, to Dr. Pauwels, head of the Municipal Orthopaedic Clinic at Aachen.

THE annual Congress of the Society for British Entomology will be held in the Manchester Museum and the University of Manchester during July 15-17, under the presidency of Prof. W. A. F. Balfour-Browne.

THE tenth International Congress of Military Medicine and Pharmacy will be held at Washington on May 7-15. Further information can be obtained from the general secretary, Colonel Harold W. Jones, 7th Street and Independence Avenue, Washington, U.S.A.

ENTRIES for the next award of the Henry Saxon Snell prize must be delivered on or before September 30, 1939, to the Secretary, Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.1. The prize was founded to encourage improvement in the construction or adaptation of sanitary appliances, and is to be awarded by the Council of the Institute at intervals of three years, the funds being provided by the legacy left by the late Henry Saxon Snell, fellow of the Institute. The prize for 1939 will consist of fifty guineas and a silver medal, and is offered for an essay describing suggested improvements in the construction or adaptation of sanitary appliances.

THE British Museum (Natural History) has recently issued (1939) a fourth edition of the pamphlet entitled "The House-fly" which forms No. 1 of the economic series of brochures. The work has been revised by Dr. John Smart, an assistant keeper in the Department of Entomology. The chief modifications, as compared with the previous edition, concern the account of preventive measures and remedies. The pamphlet is obtainable from the Director, British Museum (Natural History), London, S.W.7, price 6d.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 644.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

New Products of the Fission of the Thorium Nucleus

In a preceding communication¹ it has been shown that the 'transuranium' elements are found among the fission products of uranium under neutron bombardment. Consequently they must be lower elements, probably partly somewhere near tellurium², partly (the complementary fission fragments) in the region of ruthenium.

It was then natural to carry out similar experiments with thorium in order to see whether the fission of thorium gave rise to elements with chemical properties similar to those of the 'transuranium' elements, that is, elements which can be precipitated with hydrogen sulphide from a strong hydrochloric acid solution. No search for such elements had previously been carried out with thorium, since the formation of elements beyond uranium, from thorium, was not to be expected. So far, chemical analysis of the radioactive bodies produced in thorium by neutron bombardment has revealed (apart from a thorium and a protactinium isotope resulting from pure neutron capture) only products which, on the basis of their chemical properties, had originally to be assigned to radium and actinium isotopes³ and which have more recently been identified with barium and lanthanum isotopes⁴.

A 'thick' layer of thorium oxide on a glass plate was irradiated by neutrons obtained by bombarding a lithium target with deuterons of 800 kv. from the high-tension equipment of the Institute of Theoretical Physics, Copenhagen. In order to collect the recoil nuclei, a water surface was used in the way previously described¹. After irradiation (of about one hour) a fraction (2 c.c.) of the water was evaporated without chemical separation; with the rest (9 c.c.) the usual hydrogen sulphide precipitation was carried out in exactly the same way as in the uranium recoil experiments¹.

The precipitate showed a clearly measurable activity, the decay of which was distinctly different from the decay of the analogous uranium products. After an initial decrease with a half-value period of about 40 minutes, an activity remained which was followed for almost two days and showed a single decay period of 14-15 hours. The evaporated sample showed first a much faster decay which then gradually became slower; after two days, the activity had vanished.

A second experiment with 2.5 hours' irradiation gave the same result, with correspondingly greater intensity, especially of the longer period. In this experiment, after the sulphide precipitation, the filtrate was neutralized and the barium and lanthanum¹ were precipitated as carbonates. The carbonate precipitate decayed first with about 20 minutes and then with 4 hours half-value period, in agreement with the periods already known^{3,4}.

Analysis of the decay of the sulphide precipitate showed again the presence of a substance of half-period about 40 minutes and of one of 14.5 hours, which was followed for nearly three days and found to decay to zero. The initial intensities of the two periods were about equal, in spite of the short duration of bombardment. The possible existence of very short or very long additional periods can, of course, not be excluded on the basis of this experiment. The two periods observed are quite different from those of the chemically analogous uranium products.

Several check experiments without neutrons showed that there was no contamination of the water by thorium B or C, which might have resulted from radioactive recoil or traces of emanating thoron. As a further protective measure, the thorium layer was sealed, in the second experiment, by a celluloid membrane of 0.3 mm. stopping power.

From the evidence given above, one can conclude that some of the fission products of thorium show a chemical behaviour similar to that of the 'transuranium' elements. This is a further indication that essentially the same chemical elements are produced in the fission of uranium and thorium.

In conclusion, I wish to express my thanks to Dr. T. Bjerre, Dr. J. Koch, and K. J. Broström for kind help in the irradiations with the high-tension tube. I am especially grateful to Prof. N. Bohr for the opportunity to carry out these experiments and for the facilities kindly put at my disposal at the Institute of Theoretical Physics, Copenhagen.

Electronic Breakdown in Solid Dielectrics

In a recent paper¹ Dr. Fröhlich has advanced a theory of the electronic breakdown of ionic crystals under electric stress. The theory was applicable to diatomic crystals such as the alkali halides, but an extension to any polar crystal (made at the instigation of the Electrical Research Association) is in course of publication by Dr. Fröhlich.

The E.R.A. has conducted a number of experiments in order to determine whether electric breakdown in a uniform field, brought about in a manner such that the breakdown is independent of external conditions, is of the electronic type envisaged by Dr. Fröhlich.

A measure of agreement between theory and experiment has been obtained in respect of the following points.

(1) The absolute value of the electric strength of polar crystals may be calculated from the optical properties, the dielectric constant and the molecular volume. The theoretical value for potassium bromide at room temperatures is in good agreement with the experimental value (see accompanying graph). For mica, certain of the required constants are not known and the theoretical value is therefore uncertain; on taking probable values, however, the value of the electric strength obtained is $8.6 \times 10^6 \text{ v./cm.}$, with a possible upper limit of $15 \times 10^6 \text{ v./cm.}$ The experimental values for both sustained and impulse stresses lie within these limits.

(2) The theory predicts that the electric strength of thin sheets of insulating material should increase with decrease of thickness when the thickness is comparable with the mean free path of an electron, that is, 10^{-4} to 10^{-5} cm. The electric strength of mica has been found to increase from about $11 \times 10^6 \text{ v./cm.}$, at thicknesses from 10^{-4} to 10^{-5} cm. , to $16 \times 10^6 \text{ v./cm.}$ at a thickness of the order of 10^{-3} cm.

(3) The variation of electric strength E with temperature T (in °K.) is predicted by the theory for the simple case when there is only one residual ray frequency ν as:

$$E \propto \left\{ 1 + \frac{2}{e h / k T - 1} \right\}^{1/2},$$

where h is Planck's constant and k is Boltzmann's constant.

This form, applicable to diatomic crystals, may also be used as a first approximation for other polar crystals with several residual ray frequencies, the more accurate formulae for which are in course of publication. The electric strength should therefore increase with increase of temperature up to a critical value above which other phenomena intervene. For mica, satisfactory agreement is obtained up to about 400° K. with theoretical curves based on the assumption that the observed value is correct at room temperature and that the effective residual ray wavelength is between 10μ and 20μ . The experimental variation for potassium bromide is in the same direction as, but of greater magnitude than, that predicted by theory. The discrepancies at lower temperatures, though considerable, are, however, small in comparison with the divergences which are found with those materials to which the existing theory does not seem to apply, and where indeed a completely opposite variation with temperature frequently occurs. An example of this also is shown in the graph, by the inclusion of the electric strength of a synthetic resin varnish, determined by A. Morris Thomas and M. V. Griffith in this laboratory.

It is hoped that a complete account of these and other similar investigations will be published in due course.

Supersonic Dispersion and Infra-Red Radiation

A propos of the Herzfeld and Rice¹ theory of acoustic dispersion in gases, by which a lag in the transfer of translational energy into vibrational energy in high-frequency collisions of molecules is supposed to take place, Dwyer² has recently described experiments in which the after-effect of collisions produced when a discharge passes through a gas is evidenced by the persistence of absorption lines in the visible spectrum for a short time after the discharge has ceased. While these experiments give credence to the 'relaxation theory' in its original form, they have no necessary connexion with supersonic dispersion, since Dwyer made no supersonic experiments on the gas in question (iodine).

During the past year, I have been attacking the same problem from a different angle. Attempts have been made to find a direct effect on the well-known supersonic dispersion of carbon dioxide by subjecting it to optical radiation of its own natural (vibrational) frequencies. A Pierce acoustic interferometer was constructed of the usual type, save that the centre portion, including the region between the quartz oscillator and the reflector, was provided with quartz windows. The apparatus was evacuated and filled with carbon dioxide. Frequencies between 80 and 100 kc./sec. for the supersonic source were used, corresponding roughly to the peak of the dispersion region for the gas in question. The infra-red radiation came from a hot tube of the original Rubens and Ashkinas³ type containing carbon dioxide, and was focused by mirrors on to one of the quartz windows.

Two experiments were tried. In the first, the beam emerging from the opposite window was passed through a Hilger infra-red spectrometer and the

intensity of the 4μ , 8μ and 15μ lines of carbon dioxide compared when the quartz was quiet and when it was set in oscillation, to see if the supersonic energy caused any change in the absorption of these radiations. No positive effect was found, though this was not surprising in view of the limited amount of supersonic energy which one can get into a gas at such frequencies, and the already small residual infra-red energy after the gas had exercised its selective absorption.

In the second experiment, the gas was again irradiated at the three infra-red wave-lengths quoted and measurements made of the wave-length and dissipation of the supersonic energy in the gas. No change in wave-length, other than that which could be attributed to the rise of temperature, was found; but the supersonic attenuation was definitely greater when the gas was irradiated than when it was not, as though the molecules, excited in their natural vibrational states, were able to absorb more supersonic energy.

It is, however, difficult to generalize from this result in respect to the relaxation theory, since Penman⁴ and others have shown that a mere increase in thermal agitation of the molecules, induced by rise of temperature and irrespective of any particular natural mode of vibration, produced a change in the supersonic dispersion.

Mechanism of Excitation of the Forbidden Lines of Oxygen and Nitrogen in the Spectra of the Aurora and the Night Sky

RECENT publications concerning the identification of the ^4S - ^3P forbidden transition of NI in the spectra of the aurora and the night sky require a revision of previously published results. Actually, R. Bernard¹ has shown that the wave-length of the auroral radiation considered is undoubtedly 3466.5 ± 1 Å, instead of 3470 Å. On the other hand, laboratory² and theoretical³ determinations give respectively λ 3466.3 and 3466.5 Å. Owing to this fair agreement in wave-length, the attribution of the auroral radiation to the forbidden transition of NI may be accepted fairly safely, whereas this identification is not yet acceptable in the night sky spectrum (owing to unduly high $\Delta\lambda$).

In this communication we want to suggest a new excitation mechanism for the forbidden line of NI and for the increasing intensity of the red O I-line with height and auroral type; this mechanism does not require polyatomic compounds.

It has been shown⁴ that the auroral spectrum exhibits the system of Vegard-Kaplan bands. According to L. Vegard⁵, it is not yet proved that the intensity of these bands is increasing with height; but this may be safely assumed as the initial state is a metastable level. On the other hand, L. Vegard⁴ has observed, on many occasions, that the intensity ratio of the red and green lines increases in the spectra of diffuse auroras; this must be connected with Bernard's observation¹ of a different behaviour

of the Vegard-Kaplan bands in the auroras of the diffuse and of the other types. Finally, there must be noticed a close connexion⁶ between the Vegard-Kaplan bands and the newly identified NI transition, this meaning that the concentration of the ^3P metastable nitrogen atoms is connected with the forbidden emission A $^3\Sigma \rightarrow ^1\Sigma$.

The Vegard-Kaplan bands which have been identified with the strongest evidence⁷ correspond to the final levels $v' = 9$ to 15. If we determine the excitation energies corresponding to the vibrational states $v' = 7$ and 15 of the normal level of N_2 , we get the following figures: $E_{v'=7} = 16884.5 \text{ cm}^{-1} = 2.08 \text{ ev}$. $E_{v'=15} = 31103.4 \text{ cm}^{-1} = 4.08 \text{ ev}$. These values exceed the ^1D excitation potential of O I but are inferior to ^1S .

It is therefore justifiable to assume that by collision of a normal O I atom with a N_2 molecule which has emitted the Vegard-Kaplan bands, the oxygen atom is actually only able to be excited to the ^1D state and not to ^1S . As we know that N_2 and O I are the major constituents of the upper atmosphere (above 100 km.), it seems doubtless that collisions must happen between these two constituents. Still this mechanism requires the absence of a spontaneous emission of the vibrational bands of N_2 . This is actually the case owing to the fact that N_2 has no electric dipole. Thus N_2 molecules may spend a long time on the excited vibrational levels of the lowest electronic state, and consequently the number of excited ^1D oxygen atoms will be a function of the emission of the Vegard-Kaplan bands.

If NI atoms are present in the high atmosphere, the same mechanism explains the observation of the ^4S - ^3P forbidden transition associated with the emission of the Vegard-Kaplan bands in the spectra of diffuse auroras. As the excitation energy of the ^3P level of NI amounts to 5.56 ev., a certain number of N_2 molecules, after emission of the Vegard-Kaplan bands, will collide with the normal ^4S nitrogen atoms and bring them to the ^3P state.

A more detailed paper concerning the identification and excitation processes of the forbidden transitions in the spectra of the earth's atmosphere will appear in the *Mémoires de l'Institut Royal Météorologique de Belgique*.

Resistance-Capacity Tuning

VALVE oscillators and selective amplifiers, in which tuning is carried out by a combination of condensers and resistances, have been developed in recent years and provide means of obtaining sinusoidal oscillations of low as well as high frequency.

In an oscillator which I am developing, the lower frequency limit has been brought down one hundred-fold and more by making use of the Miller effect. The principle involved is as follows. If a condenser C be connected between the grid and cathode of a valve and a potential difference V exists between these

points, then a current I enters the condenser. Let the condenser be now connected between the grid and the anode of the valve, the grid-cathode potential being still V . The potential of the anode will be $-mV$ if the gain of the valve is m (assuming the anode and grid potentials to be in antiphase), and the potential difference across C will be $(m+1)V$. Accordingly, the current entering C will be increased $(m+1)$ times. This new current is the same as that which would be taken by a condenser of capacity $(m+1)C$ between grid and cathode. As the gain may be of the order of hundreds, the equivalent of many microfarads may easily be obtained.

Using this effect, I have built an oscillator with a periodic time of several minutes, although the largest condensers and resistances employed are 0.2 microfarad and 2 megohms respectively. With periodic times of a few seconds available, one may demonstrate the production of rotating magnetic fields, for the synchronous speed is low enough to be followed by a compass needle.

In a similar manner, the 'equivalent' resistance of a grid leak may be increased many times. An additional phase-reversing valve stage is necessary here. This possibility has not been developed, as other and simpler means for producing the same effect exist.

Polymerization of Liquids by Irradiation with Neutrons and Other Rays

IN continuation of previous work on the effects of radiations on liquids¹, we have for some time been investigating the action of neutrons, alpha-, beta- and gamma-rays in inducing polymerization of a number of hydrocarbon compounds. Of the different methods used for observing the rate of polymerization—changes in colour, refractive index, viscosity, streaming polarization, etc.—we have found it convenient to follow the changes in density consequent on irradiation by means of a volume dilatometer. The sources of radiation were sometimes placed inside the bulb of the dilatometer, and sometimes surrounded it.

POLYMERIZATION OF METHYLACRYLATE BY IRRADIATION WITH NEUTRONS AND GAMMA RAYS.

Strength of source: $\gamma = 78$ mgm. Ra [SO₄] in Pt needles 0.5, 0.6 mm. filter; $\gamma + n = 78$ mgm. Ra [SO₄] + Be in monel metal tubes, 2 mm. filter. Irradiated volume = 6 c.c.

In the case of neutron irradiation, the liquid under test was placed in a small double-walled vessel, similar to a Dewar vessel, to which a capillary stem had been sealed. The gamma-ray or neutron sources were placed in the central cavity and the whole apparatus immersed in a large bath of water. A typical series of observations during the gamma-ray and neutron irradiation of methyl methacrylate is shown in the accompanying graph. Similar results were obtained with beta-rays.

The liquids investigated so far include, in addition to methyl methacrylate, styrene, vinyl acetate, and a ketone. The expulsion of dissolved substances which had been deliberately added, for example, cresin, indole, etc., was often strikingly shown during the polymerization.

New Acetylated Derivatives of Amino Sugars

A RECENT communication from this laboratory reported the preparation of 3-amino α -methylaltroside hydrochloride and 2-amino α -methylaltroside¹. Development in this field of work has been rapid, and it therefore seems desirable to publish additional information which has been obtained since our last letter on the subject.

The material obtained by the action of ammonia on 2:3-anhydro 4:6-benzylidene α -methylaltroside has been acetylated and separated into two fractions, which prove to be 2-acetamido 3-acetyl 4:6-benzylidene α -methylaltroside (1) in sixty per cent yield, and 2-acetyl 3-acetamido 4:6-benzylidene α -methylglucoside (2) in 1 per cent yield. The production of (1) and (2) in this reaction, previously shown by Peat and Wiggins², has thus been confirmed, but the yield of (2) obtained by us shows a wide discrepancy from that claimed by the authors mentioned above.

In analogous fashion, we have found that the material obtained by the action of ammonia on 2:3-anhydro 4:6-benzylidene α -methylmannoside, followed by acetylation, may be separated into two isomeric substances which prove to be 2-acetyl 3-acetamido 4:6-benzylidene α -methylaltroside (3) in 60 per cent yield and 2-acetamido 3-acetyl 4:6-benzylidene α -methylglucoside (4) in about 1 per cent yield. Substance (4) is therefore a derivative of glucosamine.

Galactose has been converted into a 2:3-anhydro 4:6-benzylidene α -methylhexoside, which has either the gulose or talose configuration³. When this substance is submitted to the action of ammonia followed by acetylation, the product may be separated into two isomeric 4:6-benzylidene amino α -methylhexoside diacetates, (5) and (6), which have not yet been identified.

Robertson and Dunlop⁴ obtained two isomeric α -methylhexoside chlorhydrins by the action of very dilute hydrochloric acid on 2:3-anhydro 4:6-benzylidene α -methylaltroside. These substances give amino α -methylhexosides on treatment with ammonia, and when the product so obtained is acetylated, the resulting material may in both cases be separated

into two isomeric substances by means of crystallization. The α -methylhexoside chlorhydrin, m.p. 160°, yields triacetyl 3-acetamido α -methylglucoside (7)² in 60 per cent yield, and a trace of an isomer (8), which has not yet been identified. The other chlorhydrin, m.p. 188°, after similar treatment, yields (7) in 50 per cent yield and an isomer (9), which has not yet been identified, in 20 per cent yield.

A syrupy mixture of α -methylhexoside chlorhydrins has been obtained from 2:3-anhydro 4:6-benzylidene α -methylmannoside by the method mentioned above, but we have not yet been able to separate the constituents. On treatment of this mixture with ammonia and subsequent acetylation, however, a crystalline product is obtained, from which we have separated (7) in 15 per cent yield and an isomer (10) in 65 per cent yield, which differs from (8) and (9).

Finally, the benzylidene group has been removed from 2-acetyl 3-acetamido 4:6-benzylidene α -methylaltroside (3), and the product acetylated to give 2:4:6-triacetyl 3-acetamido α -methylaltroside, which proves to be identical with (10).

Constants for the derivatives described are appended.

- (1) m.p. 181–183°; $[\alpha]_D^{25} + 51.5^\circ$ in chloroform ($c = 2.13$).
- (2) m.p. 266°; $[\alpha]_D^{25} + 45.6^\circ$ in chloroform ($c = 0.56$).
- (3) m.p. 201°; $[\alpha]_D^{25} + 14.6^\circ$ in chloroform ($c = 2.33$).
- (4) m.p. 235°; $[\alpha]_D^{25} + 45.5^\circ$ in chloroform ($c = 0.85$).
- (5) m.p. 188°; $[\alpha]_D^{25} + 43.4^\circ$ in chloroform ($c = 1.25$).
- (6) m.p. 260°; $[\alpha]_D^{25} + 70.3^\circ$ in chloroform ($c = 0.87$).
- (7) m.p. 179°; $[\alpha]_D^{25} + 105.0^\circ$ in chloroform ($c = 2.12$).
- (8) m.p. 130°; $[\alpha]_D^{25} + 96.7^\circ$ in chloroform ($c = 0.74$).
- (9) 5 group; $[\alpha]_D^{25} + 50.4^\circ$ in chloroform ($c = 2.73$).
- (10) m.p. 177°; $[\alpha]_D^{25} + 24.7^\circ$ in chloroform ($c = 2.33$).

Full details of the above transformations and evidence of identification will be published shortly.

Use of *dl*-Menthol for the Preparation of Biosynthetic Glucuronic Acid

GLUCURONIC acid, within recent years, has been shown to be a compound of considerable biological importance. Besides playing an important part in the detoxication mechanisms of the body, this carbohydrate derivative is also an essential component of certain immuno-polysaccharides¹. It is found in many mucoproteins² and may be a component of the blood anti-coagulant, heparin³; furthermore, certain sex hormones of human pregnancy urine are found combined with glucuronic acid⁴. Investigations on the chemical nature and biological function of these substances, which will also involve synthetic experiments, will be greatly facilitated if glucuronic acid is obtainable in relatively large amounts. A convenient chemical synthesis of glucuronic acid, such as exists for galacturonic acid⁵, is not available. The main source of it has been biological, advantage being taken of its function in the mammal as a detoxicating agent.

A good method for obtaining biosynthetic glucuronic acid, worked out by Quick⁶, depends upon the

formation and excretion of bornylglucuronic acid following the ingestion of borneol by dogs (under the best conditions the administration of 1 gm. borneol gives 1 gm. zinc bornylglucuronate). In many laboratories, however, it may be inconvenient to keep dogs for long periods, and the collection of urine from dogs fed with borneol requires a large metal-lined cage. Rabbits, however, are much more convenient to use, and an ordinary wire cage set in a suitable funnel can be utilized for collecting the urine.

In a recent paper⁷, I showed that good yields of conjugated glucuronic acid are obtainable from rabbits fed with *dl*-menthol, *dl*-isomenthol and *d*-isomenthol. This investigation has now been extended, and it has been found that *dl*-menthol is the most suitable substance to use when relatively large amounts of glucuronic acid are required. *dl*-Menthol conjugates with glucuronic acid to the extent of 60 per cent in the rabbit, and a higher yield of conjugated glucuronic acid is obtained than in Quick's method using dogs and borneol. *dl*-Menthol (synthetic) can be purchased in large amounts and has no effect on rabbits at the dose level (8 gm.) used. It has a low melting point (34° C.) and can therefore be administered by stomach tube as a partial emulsion in a small amount of warm water. Maximal conjugation with glucuronic acid occurs on using a dose of 3 gm. per rabbit (weighing 2–2.5 kgm.) and excretion of the conjugated product is complete in about 30 hours.

The isolation of menthylglucuronic acid (as the ammonium salt) is a short and easily effected procedure⁷. Ammonium menthylglucuronate is obtained in consistent yields of 1.4 gm. per gm. of *dl*-menthol fed. Thus, on feeding 3 gm. of *dl*-menthol to each of six rabbits, 25 gm. of the ammonium salt was isolated. On suitable treatment with acid, this salt gives glucuronic acid in good yields. The ammonium menthylglucuronate ($[\alpha]_D = ca. -30^\circ$ in water), containing about 60 per cent *d*- and 40 per cent *l*-menthylglucuronic acid, can be resolved by fractional crystallization from water, and the hitherto undescribed *d*-menthyl- β -*d*-glucuronide, $C_{16}H_{24}O_7$, $1\frac{1}{2} H_2O$ (m.p. 110–112° C., $[\alpha]_D = ca. +5^\circ$ in alcohol) can be obtained. *l*-Menthyl- β -*d*-glucuronide has been previously described on several occasions.

Diaphorase I and II

WE have used the name 'diaphorase' to designate the enzyme which catalyses the transport of hydrogen from dihydrocoddahydrogenase I (CoH_2 , I) to acceptors like methylene blue or cytochrome, but not to molecular oxygen^{1,2}. This enzyme, which had been detected independently by Dewan and Green³ ("coenzyme factor"), occurs in all animal tissues so far examined as well as in yeast^{4,5} and in higher

plants'. Diaphorase from heart muscle, purified to some extent by precipitating a phosphate extract from washed tissues with low concentrations of acetone and ammonium sulphate⁴, was shown to attack CoH_2 I specifically, that is, it was inactive against dihydrocodehydrogenase II (CoH_2 II).

Recently we studied the action of crude, dialysed extracts from various acetone-dried tissues upon CoH_2 I and CoH_2 II, and found (a) that the rate at which these substances were oxidized was extremely low in all cases, which means that an auto-oxidizable enzyme of the type of the 'old' flavin enzyme probably does not occur in animal tissues, (b) that after addition of methylene blue a more or less rapid dehydrogenation of both hydrogenated ooenzymes occurred. Therefore besides the previously known CoH_2 I-specific diaphorase, a similarly acting enzyme transporting hydrogen from CoH_2 II to methylene blue is present in animal tissues. We propose to call the CoH_2 I-specific diaphorase now "diaphorase I", and the CoH_2 II-dehydrogenating enzyme "diaphorase II".

The dialysed and centrifuged water extracts from acetone-dried tissues were used. CoH_2 I and CoH_2 II were prepared by reduction of Co I and Co II with sodium hyposulphite and their dehydrogenation was followed directly by spectrophotometric observation of the disappearance of the typical absorption band at 334 m μ . A typical experiment contained 1.0 ml. m/2 phosphate buffer pH 7.2 plus 0.1 mgm. CoH_2 (I or II) plus 0.1 ml. m/1000 methylene blue plus 0.1 ml. enzyme; total volume 4.0 ml.; at the beginning of the experiment was $\epsilon_{334 \text{ m}\mu}^{\text{CoH}_2 \text{ I}} = 0.42$ or $\epsilon_{334 \text{ m}\mu}^{\text{CoH}_2 \text{ II}} = 0.38$.

The activities of diaphorase I and II are expressed by the decrease of the extinction ($-\Delta\epsilon$) at $\lambda = 334 \text{ m}\mu$ calculated for 0.1 ml. enzyme during the first 10 minutes.

Tissue	Activity ($-\Delta\epsilon$ for 0.1 ml. enzyme and 10 mm.)		$A_1 : A_2$
	Diaphorase I (A_1)	Diaphorase II (A_2)	
Heart	0.33	0.055	6
Liver	1.40	0.80	1.75
Ovary	0.14	0.10	1.4
Adrenal gland	1.45	1.50	0.97

As can be seen from the last column of the accompanying table, the ratio of the activities of diaphorase I and II (A_1/A_2) is different in various extracts, which is in accord with the view that the enzymes are not identical. Whether diaphorase II is specific for CoH_2 II or active against CoH_2 I as well, cannot be decided from these experiments, but it is clear that this enzyme is different from the CoH_2 I-specific diaphorase I. Dewan and Green's statement⁴ that "oenzyme factor" from heart muscle attacks CoH_2 II as well as CoH_2 I can now be explained by the existence of the two different enzymes.

Recently it was found in this Institute^{5,6} that heart muscle contains a flavoprotein which has the same function as diaphorase I, and Corran, Straub and Green¹⁰ suggest the identity of Straub's heart flavoprotein with diaphorase. Our experiments show that the diaphorase I and II activity of our tissue extracts is greatly reduced by precipitation with HCl-ammonium-sulphate and partly regenerated by addition of flavin-adenine-dinucleotide, in analogy

with what has been found by Warburg and Christian¹¹ for the known flavoproteins; thus diaphorase II probably is a flavoprotein.

Resonance in the External Auditory Meatus

DR. LITTLE's method of investigating resonance in the external auditory meatus¹ by replacing the air in the meatus by hydrogen is very interesting. The manner in which his results are to be interpreted, however, is not clear.

The resonant frequency will depend, amongst other things, on the length of the meatus and upon the impedances at its terminations. The frequency which he quotes for the resonance in normal human beings—2,000–3,000 cycles per second—refers apparently to the condition in which the ear is open to the air. It is somewhat surprising, therefore, that Dr. Littler should obtain a frequency of the same order in experiments in which the meatus was closed by a telephone receiver. In this condition, however, it is to be expected that the resonance will be considerably influenced by the volume of air enclosed between the ear cap and the entrance to the meatus and will be a function, therefore, of the particular receiver employed. It would be interesting to have also the results of similar experiments carried out with this volume reduced to a minimum, say, by employing a receiver of the type designed to fit into the entrance of the meatus.

I have recently made some measurements, by the probe tube method, on the resonance of the meatus when open to the air. The flexible probe tube employed had an external diameter of about 2 mm. and led to a microphone placed behind the observer's head. The ratio of the sound pressure near the ear drum to that in an approximately plane progressive wave coming from directly in front of the observer was measured. The pressure change observed is due partly to resonance in the meatus and partly to diffraction by the head. In the eight ears examined the frequency of maximum pressure increase at the ear drum varied from about 2,500 cycles per second to 4,000 cycles per second, and the maximum increase from about 9 to 15 decibels. The mean values for the eight ears are given in the accompanying table.

Frequency (cycles per second)	Ratio of pressure near ear drum to that in unobstructed progressive wave (decibels)
500	— 2
1000	— 3
2000	0
3000	12
4000	13
5000	6

In devising appropriate objective methods of measuring the gain of hearing aids, resonance of the meatus under these conditions thus requires consideration, since they are the conditions of normal hearing with which aided hearing has to be compared.

Post-Partum Estrus in a Bat

ALL the insectivorous Chiroptera in which details of the breeding cycle are known are monœstrous, producing a single offspring, or sometimes twins, once a year.

In *Nyctoris luteola* Thos. there is a post-partum estrus, so that at least two pregnancies occur in quick succession. Out of thirteen adult female specimens collected at Mto-wa-mbo, Tanganyika Territory, in December 1935, nine were in full lactation, and at the same time pregnant with fetuses up to 12 mm. in length. Two others were lactating and in estrus; and two young adults were not lactating but pregnant for the first time.

The ovaries of these bats contained no corpora lutea, which must disappear early in pregnancy. They contained many healthy ripening follicles, and presented an appearance widely different from the heavily atretic ovaries usually found in pregnant monœstrous bats. They gave every indication of being prepared for a further œstrous cycle during the forthcoming lactation period.

The genital tracts of all the adult males, collected at the same time and place, were in full functional condition. These facts point to the possibility of this species being polyœstrous.

Observations on the anatomy and physiology of the genital tract in *Nyctoris luteola* and other species of African bats will be published elsewhere in due course.

Colchicine-induced Polyploidy in Nature

IN a recent communication¹, Prof. D. Kostoff describes experiments in which he has produced a polyploid condition in seedlings grown in close association with disintegrating pieces of the corms of *Colchicum autumnale*. He further suggests that the sites of colonies of this species might prove fruitful sources of polyploids.

On examining several such sites, I have failed to find anything of an abnormal nature, in respect of external morphological characters, either in grass-like or other species. One colony was known to be at least twenty years old, and was associated with a mixed flora.

It is well known that the influence of colchicine is to delay germination and to cause stunting of growth with a delayed establishment of a root system. In the case of mustard, every seedling was affected after soaking the seed for four days in a 1:2,000

aqueous solution of amorphous colchicine. Control plants reached a height of 50 mm. after 20 days growth, whilst the treated seedlings averaged only 15 mm. in height.

In the case of rye-grass (*Lolium perenne*), colchicine appears to affect a smaller proportion of seedlings. The difference in the rate of growth and resulting height of unaffected and control seedlings, as compared with affected ones, is even more pronounced. The average height of the former individuals was 65 mm. after 28 days growth, while that of affected plants was 7 mm. with a complete absence of root growth.

It is obvious that in a state of Nature, the polyploid individuals would be suppressed in competition with normal seedlings or established vegetation. This would be quite sufficient to explain their absence in the field.

Open-Air Sites of the Upper Palæolithic Period in Kent and North Lincolnshire

FROM time to time I have recorded in the columns of NATURE the discovery of artefacts and pottery fragments in lateral valleys of the Lower Thames. The geological conditions under which these finds were made caused me to attribute to them an Upper Palæolithic date; a precedent for which is to be found in the discoveries and claims made by Mr. J. Reid Moir, as a result of investigations conducted by him at Ipswich during the past twenty years.

The prolonged and extensive excavations I have since been enabled to make in the Lower Thames Valley and elsewhere compel me unreservedly to withdraw all claims I have made for the alleged discovery of pottery of Upper Palæolithic age, and to regard the pottery in question as belonging to Neolithic - Bronze Age times.

The comprehensive series of deposits, twenty-five feet thick, exposed in the Ebbsfleet Channel, near Northfleet, has established the fact that during Middle and Late Pleistocene times south-east England was peopled by Levalloisian races and that the characteristic Upper Palæolithic cultures of the Continental caves are unrepresented.

Some years ago I directed attention to the apparent close relationship of the Ebbsfleet Channel beds to the estuarine deposits underlying the Brown or Heale Boulder Clay at Kirmington and Barton-on-Humber, in north Lincolnshire¹.

Preliminary investigations at these two sites have resulted in the discovery of two distinctive types of artefacts, namely, Clactonian and Creswellian². The former are similar to the Clactonian examples found in the Levalloisian horizons of the Ebbsfleet Channel: whilst the latter are the counterpart of the Continental cave types mentioned above, and so conform to the Upper Palæolithic series of implements found by Mr. A. L. Armstrong in the Derbyshire caves.

Thus it would appear that at Kirmington and at Barton-on-Humber there is evidence of the overlapping of these two fundamentally different implement-making techniques.

It is to be hoped that further evidence on this point may be obtained from these sites during the present year.

Storage of Radium in War Time

RADIUM is not only a valuable but also a very dangerous substance. If, during an air raid, any quantity of radium was dispersed by violence, the buildings in which it was dispersed, as well as a considerable area surrounding the buildings, would be for many years to come a menace to any people who inhabited them. One-hundredth of a milligram would probably be fatal if inhaled.

It is therefore necessary that steps should be taken to provide for the safe custody of radium in war time, and a conference has been held between representatives of the British X-ray and Radium Protection Committee, King Edward's Hospital Fund for London, the Ministry of Health and the National Radium Commission, to consider this matter.

The National Radium Commission is compiling a register of owners and holders of radium, with a view to satisfactory arrangements being made. The Commission earnestly requests all persons who have radium in their custody or possession (including the responsible official of institutions holding radium) to notify the Commission, stating the amount of radium held.

GEORGE F. STEBBING.

Points from Foregoing Letters

L. MEITNER has collected recoil nuclei resulting from the fission of thorium and has found that some of the fission products are chemically analogous to those fission products of uranium which have formerly been assigned to elements beyond uranium. The decay of the new fission products has been analysed into two exponentials with 40 minutes and 14.5 hours half-value period.

In accordance with Fröhlich's theory of electronic breakdown, A. E. W. Austen and W. Hackett find that the electric strength of polar crystals such as potassium bromide may be calculated from the optical properties, the dielectric constant and the molecular volume. Similarly, the electric strength of thin sheets of insulating material (mica) is found to increase with decreasing thickness (from 10^{-2} to 10^{-3} cm.) and also with increasing temperature up to a critical value around 400° K.

E. G. Richardson shows that the absorption of supersonics in carbon dioxide is increased by subjecting the gas to infra-red radiation of wave-lengths corresponding to the natural (vibrational) frequencies of the carbon dioxide molecule.

A new mechanism for the excitation of the forbidden nitrogen line N I and for increasing the intensity of the oxygen line O I with height and according to the type of the aurora, is suggested by M. Nicolet, who states that, after the emission of the Vegard-Kaplan bands, the nitrogen molecules can excite the atom O I and bring it to the metastable state ^3D , and the atom N I to the state ^3P .

The Miller effect has been employed by N. H. Roberts to increase the periodic time of oscillations obtainable from valve oscillators using capacity-resistance tuning.

F. L. Hopwood and J. T. Phillips record the polymerization of a number of unsaturated liquid hydrocarbons by neutrons and ionizing radiations. They submit a graph illustrating the difference in the rate of polymerisation of methyl methacrylate when irradiated by two similar sources of gamma rays, of which only one has a marked neutron emission.

A number of new acetylated derivatives of amino hexoses, in which the amino group is attached in the 2 or 3 position in the carbon chain, have been isolated by G. J. Robertson and W. H. Myers. One of them proves to be a derivative of glucosamine.

R. T. Williams states that when *d*-menthol is administered to rabbits, 60 per cent of it is excreted in the urine combined with glucuronic acid. Menthyl-glucuronic acid is easy to isolate from the urine in excellent yields as the ammonium salt. This salt contains unequal amounts of *d*- and *l*-menthol, the *d*-form predominating.

Animal tissues contain besides the known diaphorase I, which transforms dihydrocodehydrogenase I from dihydrocodehydrogenase I to methylene blue or cytochrome, which catalyses the analogous reaction of dihydrocodehydrogenase II, according to Adler, H. v. Euler and G. Günther. The new enzyme, for which the name "diaphorase II" is proposed, is probably a flavoprotein.

Commenting on Dr. Littler's communication on resonance in the auditory meatus, N. Fleming directs attention to the influence of the conditions at the entrance to the meatus, and gives results of some measurements, by the probe tube method, with the meatus open to the air.

L. Harrison Matthews records the occurrence of a post-partum oestrus in *Nyctotis luteola*, an East African bat, and points out the species being polyoestrous.

An examination of sites of *Colchicum* failed to reveal anything of a morphological or abnormal nature in the associated flora. It is suggested by G. H. Bates that the influence of the distigating corms in producing polyploids, as demonstrated by Kostoff, would be nullified by the suppressing effect of the taller normal species.

As the result of extensive excavations in the Lower Thames valley and elsewhere, J. P. T. Burchell withdraws previous statements concerning the discovery of pottery of Upper Palaeolithic age, which he now considers as belonging to Neolithic - Bronze Age times.

Research Items

Duration of Life in Early Man

PROF. F. WEIDENREICH supplements the recent conclusions of Prof. H. Vallois as to the duration of life in Neanderthal, Late Palaeolithic, and Mesolithic man (see *L'Anthropologie*, 47, 499; 1937: *NATURE*, 141, 292; 1938) by an examination of the question of age in relation to Peking man and Late Palaeolithic man as occurring in China. At the same time he analyses the evidence bearing on the cause of death and the incidence of disease in this population, so far as it is known. The most adequate information relating to the age of individual specimens is to be derived from the state of the sutures of the skull. Out of 38 individuals of *Sinanthropus* now known, of whom fifteen are juvenile, seven only provide skulls sufficiently well preserved to afford evidence. Of these, three belonged to individuals aged less than thirty years, three may range between thirty and forty years, and only one, apparently that of a female, may have been really old, more than fifty, or even sixty years. Within the *Pithecanthropus* group two skulls show complete fusion of the sutures of the skull-cap, pointing to an age of more than fifty years. The recently discovered third skull is juvenile. It is possible, however, that the time of the fusion of the sutures may not correspond to that in modern man. In the anthropoids it is earlier. This would merely serve to confirm the conclusion that the actual duration of life in *Sinanthropus* was shorter than in modern man. With regard to Late Palaeolithic man in China, of the group of seven individuals known from the cave of Choukoutien, the state of the sutures indicates that three were juvenile, and of the four adults, two, probably women, were slightly more than twenty years, the age of the third cannot be determined, though it probably was not advanced, and the fourth was certainly an old man, at least sixty years of age. These figures compare with those of Vallois for the Western world. In both *Sinanthropus* and Late Palaeolithic man, an advanced age was seldom reached; while in both classes of remains from China, the evidence of the skulls indicates a death from violence and not old age or disease.

Factors affecting Sex in a Japanese Beetle Parasite

M. H. BRUNSON, of the U.S. Bureau of Entomology and Plant Quarantine, has recently issued a paper on this subject (*J. Agric. Res.*, 57, No. 5, 379; 1938). It appears that the parasite in question, namely, *Tiphia popilliae*, like its host, has a single generation annually. The Japanese beetle passes through three larval instars and, of these, the second and third are utilized by the female *Tiphia* for purposes of oviposition. Preference, however, is shown for those in the third instar. Adult parasites which emerged from cocoons, formed on second instar hosts, were predominantly males, while those obtained from parasitized third instar larval hosts were largely females; the ratio of females in the two cases being, in percentages, 6.4:87.2. Parasite eggs transferred from second instar to third instar larvae gave a preponderance of males while the reverse transfer produced more females than males, indicating that the sex of the progeny is determined at the time the egg is placed on the host.

Insects of Eastern Ruwenzori

IN 1934 the Trustees of the British Museum appointed two members of the British Museum staff—Dr. F. W. E. Edwards and Dr. G. Taylor—as leaders of an expedition to study the flora and insect fauna of Eastern Ruwenzori. The expedition received support by way of grants from the Percy Sladen and Godwin Funds, the Uganda Government and Mme. de Horraack Fournier. The leaders proceeded to East Africa in September 1934 and returned in March 1935. While in Africa they were joined by several other workers, who assisted in carrying out the aims of the expedition for varying periods. It is noteworthy that, as in the case of other high mountains, Ruwenzori provides numerous examples of species of insects which are either short winged (brachypterous) in the female or in both sexes. Such species were found in the Geometridae and Tineidae among moths and in six different families of flies. Apart from this phenomenon of 'brachypterism' no obvious cases of adaptation to mountain conditions among insects were noted, and nothing to correspond with the giantism of some of the plants. The results of the expedition are in course of publication by the British Museum. Vols. 1 and 2 are to deal with the Diptera, while insects of other orders are to form the subject of vol. 3. The parts published up to date belong to vols. 1 and 3 and are sold by the Museum separately. These are Introduction; Simuliidae (E. G. Gibbons); Mosquitoes (F. W. Edwards and E. G. Gibbons); Psychodidae (A. L. Tonnoir); Ceratopogonidae (J. W. S. Macfie); Trichoptera (M. E. Mosely); Siphonaptera (K. Jordan); Rhopalocera (A. G. Gabriel); Lymantriidae (C. L. Collette); Ephemeroptera and Neuroptera (D. E. Kimmins).

Amphidiploids and other Hybrids in Tobacco Species

AN extensive cytogenetical study of hybrids between *Nicotiana glauca* and *N. Langsdorffii* has been made by D. Kostoff (*J. Genetics*, 37, No. 1) with various results bearing on the evolutionary significance of amphidiploids. *N. glauca* has $2n = 24$ chromosomes and *N. Langsdorffii* $2n = 18$ with differences in chromosome morphology. Abnormal meiosis was induced in both species by acenaphthene. The cross *N. glauca* $\times$ *N. Langsdorffii* is much easier to make than the reciprocal, but crossability depends partly on age of the plant and such conditions as temperature. The F_1 is intermediate in most characters, with 25 per cent of dwarfs in some crosses, and all the plants form non-parasitic tumours, the cells of which have mostly 21 chromosomes like the normal tissues. A small amount of monads and dyads are found in the F_1 pollen, varying with the genotype and the environment. When back-crossed to *N. Langsdorffii* most of the plants had 30 chromosomes ($12 + 9 + 9$), but one was amphidiploid. It probably arose parthenogenetically from a monad megaspore, and in meiosis it formed bivalents, trivalents, quadrivalents and univalents. The original amphidiploid had 51 per cent viable pollen. By the F_2 this had increased to 99.5 per cent, and the seed fertility showed a corresponding increase. The offspring were not constant, but showed segregation in leaf and flower size and shape, alkaloid and citric acid content,

pollen colour, etc., the chromosome numbers ranging from 21 to 52. Changes in the satellite chromosomes showed that translocations had also taken place. Thus inconstant amphidiploids may give rise to a polymorphic species which is physiologically isolated, but in which rapid evolution can take place through natural selection among the progeny. Triple species hybrids are also described with *N. Sandera* ($n = 9$).

Geology of the Lake Rudolf Basin

THE geological results of the Lake Rudolf Rift Valley Expedition have recently been recorded by V. E. Fuchs (*Phil. Trans. Roy. Soc., B*, No. 560; 1939). The lake has usually been considered to lie in the northern continuation of the Kenya Rift Valley; but it has now been found that this belief is only partly true, for though the lake occurs in a region affected by rifting movements, it does not in a proper sense lie within a rift valley. The history of the area is traced from the time when it formed part of the great Central African peneplain. In late Oligocene times the latter was fractured to form the Uganda escarpment. Renewed movement took place in the Pliocene, which resulted in a series of prominent scarps. In numerous sections evidence is found that the faults may be due to compressional rather than tensional forces. It is found that after the extensive plateau eruptions of the early Miocene, volcanic activity became more restricted and almost ceased by the beginning of the Pleistocene. Later, accompanying a renewal of movement in the Pleistocene, further volcanic outbreaks occurred. Within recent times the Telaki and Andrew volcanoes have been active and there are also signs that Central and Höhnel Islands are not yet completely quiescent. The rise and fall of the lake during Pleistocene times is discussed in conjunction with the human cultures associated with the lake beaches. An attempt is made to correlate the events within the Lake Rudolf Basin with those already known to have occurred elsewhere within the East African Province. The report is well illustrated and has an attractively coloured geological map, which, though provisional, is nevertheless of great value.

Calculation of Geological Age

WITH the increasing interest in the determination of the geological ages of minerals and rocks by radioactive methods, and the recent development of greatly improved techniques, it has become essential to reconsider the methods of calculation. This task has been adequately undertaken by N. B. Keevil (*Amer. J. Sci.*, 237, 195; 1939). New equations are developed for computing ages from chemical and radioactivity data, and errors in some of the past work are pointed out. The simple form of equation involving uranium and thorium with either helium or lead yields a good result for young rocks, but it can now be made much more accurate by taking into consideration the actino-uranium series and introducing more recent values for the radioactive disintegration constants. By a suitable choice of equations and successive substitutions, any desired degree of accuracy (assuming the experimentally determined parameters to be correct) can be attained, and at higher ages a new equation, which corrects the results by means of a constant involving the thorium/uranium ratio, can generally be applied. It is pointed out that if an

average value of 3 is adopted for this ratio, the errors introduced into the calculated ages for ordinary rocks are less than those involved in experimental measurements and in changes in the rock since its consolidation.

A New England Hurricane

DETAILS concerning the tropical hurricane that passed across Long Island on September 21, 1938, are given in a paper entitled "Hurricanes into New England", by Charles F. Brooks, that has been reprinted from the *Geographical Review* of January 1939 by the American Geographical Society. This hurricane is held to have developed from a relatively weak cyclonic circulation which was in evidence on September 13 in lat. 19° N., long. 37° W., and to have originated near the Cape Verde Islands where other storms have been known to originate, between the north-east trade winds and the south-west monsoon. The fact that it reached such a high latitude without having lost the characteristics of a well-developed tropical storm—the calm central 'eye' and surrounding ring of hurricanes—appears to have been due partly to the presence of moist tropical air in its northward path after leaving the tropics, and partly to the existence of a favourable field of pressure over the North Atlantic. There was in fact a well-developed anticyclone south of Newfoundland and a trough of low pressure extending from south to north over the eastern part of the United States. The complete statistics of the destruction caused by the storm—about 600 lives lost, more than 15,000 buildings destroyed, and economic loss estimated at 250,000,000 dollars or more, place the storm in the front rank of historic storms in New England, and the economic loss as being in excess of anything previously recorded. The lowest pressure reading reported by a land station was 27.94 in. at Bellport, on the south shore of Long Island. At Blue Hill Observatory a speed of 186 miles an hour was recorded by a 3-cup anemometer; at Mount Washington there were hourly winds of more than 118 miles and gusts up to 163 miles an hour, although the storm had weakened a little when it had reached the north of New England. New York City was sheltered to some extent by Long Island, but on the top of the Empire State Building (1,248 ft.) there were gusts up to 120 miles an hour.

Reaction between Nitric Oxide and Oxygen

THE oxidation of nitric oxide by oxygen, $2\text{NO} + \text{O}_2 = 2\text{NO}_2$, has been the object of much investigation and is still not fully elucidated. E. M. Stoddart (*J. Chem. Soc.*, 5; 1939) finds that Baker's experiments on the non-interaction between the intensively dried gases can be repeated if it is arranged that mixing occurs only in the bulb containing the oxygen. Water has no effect on the non-reactive gases, so that the inhibition of the reaction seems to be wholly due to surface conditions of the containing vessels. It is supposed that drying removes adsorbed water from the glass surface, and the surface then adsorbs a complete gas film. If this film is oxygen, no reaction occurs between the mixed gases, but reaction is possible when it is nitric oxide. When the non-reactive gases are displaced from a vessel previously filled with oxygen into a new flask, reaction at once occurs. It is concluded that the reaction is not a termolecular homogeneous reaction as found by Bodenstein, but that a complex $(\text{NO})_2$ is formed by

a heterogeneous reaction and then reacts homogeneously: $\text{glass}(\text{H}_2\text{O}), 2\text{NO} = \text{glass}(\text{H}_2\text{O}) + (\text{NO})_2$; $(\text{NO})_2 + \text{O}_2 = \text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$. The negative temperature coefficient of the reaction is explained by the dissociation of the nitric oxide complex: $(\text{NO})_2 = 2\text{NO}$.

Resistance of Gold and Silver at Low Temperatures

THEORIES of electrical conductivity predict that a magnetic field will always cause an increase in resistance, but in the case of gold a decrease was found by Giaque, Stout and Clark (1937). J. W. Stout and R. E. Baricau (*J. Amer. Chem. Soc.*, 61, 238; 1939) have confirmed this result. The electrical resistances of gold and silver wires were measured at temperatures from 1.5° to 20° K. and in magnetic fields up to 8,000 gauss. The resistance and its magnetic coefficient of the silver wire were independent of temperature at the lowest temperatures. As the temperature rises, the resistance was found to increase and its magnetic coefficient to decrease. The gold wire had a minimum resistance about 7.7° K. and the magnetic coefficient of resistance was a maximum at this temperature. The magnetic field tends to eliminate the minimum in resistance. Extrapolation of the measurements indicates that at 1° K. the magnetic coefficient would become zero and below this temperature would be negative.

Petroleum Fuels in Canada

THE Canadian Department of Mines has issued another bulletin (No. 794) giving statistics of petroleum fuels delivered for consumption in Canada during the year 1937. This may be regarded as a companion volume to bulletins 772, 780 and 789 giving similar and directly comparable statistics for the years 1933, 1934, 1935 and 1936. In 1937, 1,338 million Imperial gallons of petroleum products were delivered, consisting of 589 million gallons of fuel oil, 30 million gallons of kerosene and 719 million gallons of gasoline. In addition, more than 48 thousand short tons of petroleum coke were consumed in refineries. More than 91 per cent of the fuel oil was processed in Canadian refineries (as compared with 89 per cent in 1936 and 85 per cent in 1935), the remainder being imported. The proportions allocated to domestic heating, industrial heating and power, tractor fuel, and fuel for rail and water transport were practically the same as for 1936. Kerosene deliveries in 1937 represented only one forty-third of the aggregate of all petroleum fuels as compared with one thirty-third in 1935 and 1936. Approximately 4.1 million gallons less were delivered in 1937 than in 1936. Of the total of 29.9 million gallons delivered, about 75 per cent was used for domestic purposes, 21 per cent for tractor fuel and the remaining 4 per cent for other general uses. The provisional assessment of the quantity of gasoline sold in Canada for all purposes during 1937 shows an increase of more than 194 million Imperial gallons as compared with 1936.

The Escher Wyss Variable-Pitch Airscrew

C. KELLER has recently given a full account of a variable pitch airscrew which has many advantages (*Escher Wyss News*, 11, No. 4; 1938). The incentive to the new design was given by research carried out at the aerodynamic laboratory of the Federal

College of Technology at Zurich. The research laboratory is under the direction of Dr. Ackeret in collaboration with the Federal Air Force. Keller states that a variable-pitch airscrew is an essential accessory to modern aeroplanes for increasing the efficiency of the airscrew and its propelling force. It is practically impossible to design a good propeller of the old type with fixed blades to comply with the demands on the propeller at the lowest and highest velocities of flight. This is due to the fact that, especially at great velocities, a deviation of the blades from the correct angle of incidence results in disturbing effects which lower the efficiency of the airscrew. The increase of the propelling force and of the airscrew due to the provision of adjustable blades is so considerable that the variable pitch type of airscrew is superseding the older types. A special feature of the variable-pitch airscrew is its possible braking effect during the landing run. If the blades are turned in the closing sense to such an amount as to obtain a negative angle of incidence, a negative thrust is produced and thus a braking effect to the forward motion of the aeroplane. The direction of rotation of the airscrew and engine remain constant, and hence the output of the engine itself is utilized to retard the forward motion of the plane, whereas in the old type of propeller the output of the engine was not made use of on landing. In this way the length of the landing run can be considerably reduced and if the aeroplane has more than one engine the ease with which it can be manoeuvred on the ground is considerably increased; any tendency to overturn is also effectively counteracted.

Separation of the Isotopes of Chlorine

K. Clusius and G. Dickel recently described a new process for the separation of isotopes, which was based on the combined effect of thermo-diffusion and thermo-siphon action (*Naturwiss.*, 26, 546; 1938). The process has been further improved, and the results of experiments on the separation of the isotopes of chlorine are now reported (*Naturwiss.*, 27, 148; 1939). Using hydrogen chloride and a separation tube 36 m. long, 8 c.c. of hydrogen chloride containing more than 99 per cent of HCl^{37} were obtained daily. On the 'light' side of the apparatus, hydrogen chloride containing chlorine of atomic weight 35.147 was obtained, and on another occasion chlorine of atomic weight 35.06. The authors have also used the apparatus for the separation of other liquids. With a temperature difference of 80° between the hot and cold walls of the apparatus, and using decinormal sodium chloride solution, a 3.8-fold increase in concentration of the solution at the 'heavy' end was obtained after 4 hours action. It is to be expected that different ions would migrate at different speeds owing to their varying degrees of hydration, so that a selective change in concentration should take place in solutions of many electrolytes. A mixture of acetone and water containing 42.2 mol. per cent of acetone gave after six hours and a temperature difference of 40° , a mixture containing 6.2 mol. per cent of acetone at the 'heavy' end. It is noteworthy that in spite of the low molecular weight of water in its monomeric form, it collects preferentially at the 'heavy' end of the apparatus, thus indicating the polymeric structure of water. A mixture of light and heavy water was also partially separated by the use of the apparatus.

A Derived Patterson Analysis of the Skeleton of the Cyclol C_8 Molecule

By D. P. Riley, Department of Mineralogy, Oxford, and I. Fankuchen, Birkbeck College, London

RECENT publications by Wrinch¹, and in particular by Wrinch and Langmuir², have suggested that the Patterson analyses obtained by Crowfoot³ for air-dried insulin crystals can be interpreted with some precision if one assumes that the basis of the structure of the insulin molecule is the skeleton of the Wrinch cyclol C_8 . Criticisms of their work were made by Bernal at a recent meeting of the Physical Society and in a recent letter in *NATURE*⁴. We have done the work reported here in order to answer, if possible, two questions. How well do the equivalent points chosen by Wrinch and Langmuir represent the cyclol C_8 structure? Does the cyclol fabric give a Patterson diagram resembling the one obtained experimentally? To do this, the separate atoms of the cyclol skeleton were considered and the appropriate Patterson analysis derived from their interatomic vectors.

It must be made clear that only the carbon and nitrogen atoms of the skeleton have been considered. No account has been taken of the side-chains, oxygen or water that Wrinch postulates, and reasons why these omissions should not affect the general validity of the work will be given later. Even so, this derivation was very laborious owing to the large number of atoms in the cyclol skeleton. The first step was to plot a projection of the cyclol network on the basal plane (Fig. 1). The atoms fall very closely on to a hexagonal net, and according to the number of atoms projecting on to a given point on this net, that point

Fig. 1.

PROJECTION ON THE BASAL PLANE (0001) OF THE CARBON AND NITROGEN ATOMS OF THE CYCLOL C_8 SKELETON.

Fig. 2.

DERIVED PATTERSON ANALYSIS FOR ONE C_8 MOLECULE CONSIDERED BY ITSELF.

Contour lines at one unit apart. Crosses mark positions of peaks given by an octahedral arrangement of scattering masses at the 'slits' of the cyclol fabric.

is assigned a weight of 1, 2, 3 or 4. No distinction is made between carbon and nitrogen atoms, owing to the relatively slight difference in their scattering powers. Co-ordinates were assigned to the points in the projection and the Patterson analysis derived as follows. The co-ordinates of a point in the Patterson analysis corresponding to an interatomic vector were obtained by a subtraction of the atomic co-ordinates on the projected network, and the height of the Patterson point is the product of the weights assigned to the points in the projection. By summation the heights of the various points in the Patterson analysis were obtained, and contour lines were then drawn. A derived vector analysis for one C_8 molecule considered by itself was thus obtained (Fig. 2).

The diffuse nature of the pattern should be noted. It exhibits only two weak peaks in each sixth part of the pattern, which form part of a ridge composed mainly of vectors between atoms in different sides of the atomic projection. Such a result indicates that the skeleton of the cyclol molecule cannot be approximated by an octahedral arrangement of scattering masses situated at the slits (that is, at the corners of the basal projection). Such an arrangement gives the hexagonal peak system shown superimposed on the derived analysis in Fig. 2 and the lack of fit is obvious.

The next point to be considered is the vectorial interaction between neighbouring molecules. Wrinch places the molecules (cyclols) with their centres 40 Å. apart and with a tilt of 6° . If this be done with the derived Patterson analysis of the cyclol fabric, the vector map shown in Fig. 3 is obtained. This pattern

also is very diffuse, showing weak peaks (*A*) situated approximately at the mid-points of lines joining origin peaks, and with regions of low density (*B*) situated around the centres of the equilateral triangles the apices of which are the origin peaks. This vector map should be compared with Crowfoot's experimentally derived analysis³. Here, in marked contrast to Fig. 3, there are regions of low density (*O*) at the mid-points of lines joining origin peaks, and a peak system (of which *B* is one peak) around the centres of the equilateral triangles. Such a fundamental dissimilarity clearly shows that the X-ray data for insulin are not readily explained by the cyclol hypothesis as Wrinch and Langmuir claim.

It may be argued that, as we have taken no account of the side-chains in the cyclol molecule, our results are not conclusive or even significant. We do not think that this is so for the following reasons. The cyclol fabric contains approximately one third of the mass of the molecule, the remaining two thirds being contributed by the side-chains, oxygen and water present. A projection derived from the fabric alone could reasonably be expected to bear some resemblance to that due to the whole molecule. Moreover, a certain number of the side-chains are in a direction roughly perpendicular to the plane of the projection and therefore cannot alter the fundamental pattern of the vector map. The other side-chains will cause a maximum difference to the pattern when extending out from the sloping faces of the cyclol cage, that is, towards the periphery of the projection on the basal plane. Hence the peaks would probably be moved out a little along the ridges, but this effect may well be masked by the general blurring of a pattern already diffuse. We are therefore of the opinion that the fundamental pattern of six ridges in the directions shown in Fig. 2 would not essentially be altered by a consideration of the side-chains, and we consider that a similar blurring effect would be the only contribution of the majority of the water molecules present. In any event, we have been concerned only with testing the vectorial properties of those parts of the cyclol molecule which have definitely and precisely been worked out by Wrinch, that is, the atomic skeleton of the fabric, and it is this skeleton which is the essential feature of the theory.

It is therefore indicated that:

(1) The cyclol fabric cannot adequately be repre-

Fig. 3.

DERIVED PATTERSON ANALYSIS OF THE CYCLOL MOLECULES ARRANGED IN THE UNIT-CELL OF INSULIN.

Contours at one unit apart. A is a peak and B a low density region.

sented by the set of equivalent masses chosen by Wrinch and Langmuir.

(2) Even if this representation were correct, the vector maps obtained from these equivalent points do not fit the experimental data if all the vectors are taken into account (Bernal⁴).

(3) The vector map derived from a consideration of the atomic skeletons of the cyclol molecules in the unit-cell does not fit the Patterson analysis of insulin as found experimentally by Crowfoot.

It can consequently no longer properly be claimed that the X-ray evidence furnishes any direct confirmation of the cyclol structure proposed for insulin.

Summary.—Vector maps of the carbon and nitrogen atoms of the skeleton of the cyclol C₂ molecule have been derived. From a consideration of these maps it is shown that the X-ray data obtained by Crowfoot cannot be considered as affording any direct evidence for the cyclol structure proposed for insulin by Wrinch.

Transfusion in Petrogenesis*

THIS memoir is probably the most instructive contribution to modern petrology since Brögger published his description of the Oslo area (1931)¹. It describes the north-eastern (British) part of the Birunga lava-field—a region of Tertiary and Recent vulcanism which produced 'alkali' lavas of basic to intermediate composition. The field extends along, and partly across, the Western Rift depression for some fifty miles north and north-east of Lake Kivu.

The 'alkali' character of the Birunga lavas was

first recognized by Finckh (in 1912)², from whose descriptive work fifteen analyses are cited in this memoir.

The Bufumbira lavas are referred by the authors (and their co-workers on the field-staff of the Uganda Geological Survey) to the following main groups or series:

- (1) Olivine-leucitites (that is, 'leucite-basalts') grading into olivine-rich types for which the group name 'ugandite' is proposed.
- (2) Types related to a 'melilite-felspathoidal group' known in other parts of the Birunga field.
- (3) Leucite-basanites.
- (4) Potash-trachybasalts—closely related to (a)

* Geological Survey of Uganda. Memoir No. 3: The Volcanic Area of Bufumbira. Part 2: The Petrology of the Volcanic Field of Bufumbira, South-West Uganda. By Prof. Arthur Holmes (Petrology) and Dr. H. F. Harwood (Chemical Analysis). Pp. xiv + 300 + 5 plates. (Intabbe: Government Printer, 1937.) 21s.

potash-trachyandesites (or latites), and (b) a limburgite-trachybasalt series.

Plutonic rocks occur only as ejected blocks or as corroded fragments enclosed in the lavas. Nevertheless, this scanty material has yielded striking, and often decisive, evidence supporting the important conclusions drawn from the genetic study of the Bufumbira suite as a whole.

A variation diagram (Fig. 3) based on twenty-four new and unusually detailed rock-analyses reveals four roughly linear sequences which, in the basic range, are so intimately linked by bridging terms as to constitute a field of kindred variants. All these sequences converge, at their melanocratic ends, towards a single point—represented by biotite-augite-peridotite.

As a few occurrences of types reputed to be 'true basalts' had previously been recorded from Birunga, the authors took the precaution to check the validity of the description, and they now announce that, with one exception (and even this was found to contain identifiable leucite), every lava previously described as 'basalt' contains more potash than soda and that, as in the Toro-Ankole field of the same igneous province, true basalts are absent from Bufumbira and are unknown from the Birunga field as a whole. A discovery of such fundamental importance in any genetic discussion of the Bufumbira suite raises a lively and critical interest in the authors' quest for genetic evidence.

Finckh assumed the suite to be differentiated from (a) an older 'monzonitic' and (b) a younger 'theralitic' magma. But the authors of this memoir show, convincingly, that the parental status of the two initial magmas presumed by Finckh cannot be sustained: their character, as derivatives from more fundamental units, is repeatedly exposed.

In an earlier (1932) monograph, Prof. Holmes showed that, in the Toro-Ankole field at least, genetic processes could not have involved the co-operation of either basaltic or granitic magma. On the other hand, geochemical peculiarities common to both the Toro-Ankole suite and kimberlite led him to suggest that peridotite-magma might conceivably be in parental relation to both. This hypothesis, which required also the co-operation of peridotite-with basalt-magma, was soon abandoned: Prof. Holmes adduced new data (abstracted in pars. 177 and 752) which rendered the theory untenable. On grounds detailed in the 1932 monograph and recapitulated in this memoir (pars. 758-762), it is shown that carbonate-syntaxis can have no application to the potash-rich lavas and tuffs of Toro-Ankole and Bufumbira.

As Prof. Holmes remarks, genetic hypotheses proposed for rocks of the Bufumbira type are numerous; but none has as yet met with anything approaching general acceptance. Quoting from the memoir (p. 243): "The fundamental source of the difficulties lies in the fact that petrology is concerned with an integration of complications which lies far beyond the scope of present-day physical chemistry. We must, therefore, be temporarily content with empirical hypotheses and we must regard them, not as a substitute for thought, but as a stimulant to further exploration, research, comparison, and correlation. Any hypothesis which shows signs of becoming classical—that is, of deriving its sanction from weight of external authority long after the 'pattern' of facts has expanded—tends to hypnotize its adherents and should be vigorously scrutinized in the

light of every new observation. A fruitful hypothesis is one which reveals previously unsuspected mysteries, not one which hides them".

In the Bufumbira case, the four chief theories now current are shown to be untenable. Hence, the hypothesis finally proposed, and particularly the evidence adduced to support it, are likely to be scrutinized by critical readers with more than ordinary interest.

The conclusions reached by Prof. Holmes may be said to insinuate themselves on the reader from the moment he appreciates the field-setting and implications of glimmerite (biotite-rock) in relation to biotite-pyroxenite and its allies (p. 31, 51-59, etc.). The case clarifies itself as the marshalling of evidential fact proceeds. The genetic hypothesis awaited is formulated in the concluding chapter (xii), after a brief review of recent field studies which demonstrate, unequivocally, the feldspathization of quartz and quartzite, and the granitization of sediments, schists, etc., by alkali-carrying emanations—immigrant either from magma or from solid-rock systems undergoing magmatization. Here, it would seem that the concept of a 'fundamental granite magma' fades completely out of the picture: energized emanations alone remain. The factors involved are generalized by the authors in the following scheme:

(a) Incoming emanations—from other 'active' magmas or the 'substratum', *plus*

(b) Energy (secular, radioactive, ionic reactions, etc.), *plus*

(c) Crustal rock-material—metasomatized, migmatized, or more or less magmatized by (a) and (b), *minus*

(d) Outgoing emanations and associated energy—with effects which include pneumatolysis and many features characteristic of hydrothermal ore-deposits, mineral veins, etc., together with those mentioned in (c) above.

The activating emanations already traced by the authors are "protean in their geochemical range and widely variable in their capacity for transporting and localizing energy. The combination of pre-existing rocks and emanations promises possibilities as manifold as the rocks and ore-deposits to be accounted for" (p. 277).

Transfusion, as a petrogenetic process, is fully appreciated by Fennoscandian geologists and others specially interested in the fundamental crystalline schists and associated injection-complexes. Prof. Holmes' precise, brilliant exposition of the process vindicates those geologists of the French school, and notably Michel-Lévy and Lacroix, who were probably the first to attribute certain aspects of assimilation and hybridization to the transfusion process. The mechanism, described in various ways according to the point of view adopted, has been acknowledged in principle by many leading petrologists who have contributed to the literature describing the evolution of quasi-magmatic rocks from pre-existing solid phases.

The detail and precision which characterizes Prof. Holmes's descriptive work; the discernment manifest in the grouping and alignment of Bufumbira types; the wealth of petrological fact he has co-ordinated, and his masterly integration of evidence to the far-reaching conclusions drawn make this memoir the most outstanding contribution to modern petrology yet published.

Conference on Fruit Juices and Syrups

A CONFERENCE and working demonstration on pure fruit juices and syrups was held at the University of Bristol Research Station (which is associated with the Ministry of Agriculture and Fisheries) on March 23. More than a hundred visitors attended the conference. The conference comprised four papers dealing with various aspects of fruit products developments. Prof. B. T. P. Barker, the director, referred to the association of the Long Ashton Station with fruit products research since its inception as a Cider Institute. The production of apple jelly and the pulping of soft fruits by the cold sulphur dioxide method were contributions made by the Station during the Great War period, and in more recent years the Station had commenced a comprehensive investigation into the whole question of the utilization of surplus and low grade fruit.

World developments in fruit juices were discussed by Mr. Roger Morel, secretary of the English Apple Juice Producers' Association, and the enormous annual consumption of juices in Switzerland, Germany and the United States (8, 17 and 100 million gallons respectively) were mentioned.

Mr. Christopher Norbury emphasized the urgent need for the introduction of a series of legal definitions for the strict standardization of all liquid fruit products.

Mr. Vernon L. S. Charley, in charge of the Fruit Products Section of the Station, gave a brief account of the various methods of manufacture and referred to the Long Ashton processes for apple juice and fruit syrups which had been in successful commercial use for three years. He laid special emphasis on the nutritional value of pure fruit juices and syrups,

pointing out that, though sucrose was used in the various processes, the final products as sold to the consumer contained only levulose and glucose, which are the most easily assimilable forms of sugar. The mineral contents of these pure products was such that, despite the organic acids present, the high proportion of potassium and sodium oxides tended to build up an alkali reserve in the system. Although apple juices retain only a small proportion of the ascorbic acid (vitamin C) of the fresh fruit, black-currant syrup is a very rich source of this vitamin, quantities up to 100 mgm./100 gm. of syrup having been found in syrups after twelve months' storage. Mr. Charley suggested that in times of national emergency canned black-currant syrup would assume a considerable importance in view of the possibility of the cessation or restriction of imports of fresh citrus fruits or juices. It was also pointed out that practically the whole of the nutritional value of fresh apples is retained by the processed juices.

In conclusion, details of the use of pure fruit juices and syrups for medicinal purposes were given. In Germany, inflammation of the lungs, diabetes, fevers and a number of other diseases were being treated with juices. In England, Mr. Charley referred to two series of cases in which children suffering from 'pink' disease, and adults and children being treated for hyperacidity with ulceration of the duodenum, had received great relief and in many cases had been cured by the use of apple juice ('pink' disease) and black-currant syrup (ulceration cases).

Working demonstrations enabled the visitors to observe the various cold and hot processes for the production of apple juice.

Lord Rutherford: His Life and Influence on Chemistry

SIR HENRY TIZARD delivered the first Rutherford Memorial Lecture of the Chemical Society on March 29. He began by referring to Rutherford's early life at Cambridge, where he came in 1895 from New Zealand with an 1891 Exhibition. Continuing work on the detection of electrical waves which he had begun in New Zealand, Rutherford was able within a year to receive signals at a distance of half-a-mile; this work was described and demonstrated at the meeting of the British Association in 1896. The discovery, however, of X-rays and of the radioactivity of uranium shortly after his arrival at Cambridge determined his life's work, and he became associated with J. J. Thomson in work on the ionization of gases by X-rays and on the electrical conduction caused by uranium radiation.

In 1898, at the early age of twenty-seven years, Rutherford was appointed to the chair of physics at McGill University, Montreal, where he was joined by Soddy in investigations demonstrating that radioactivity is an atomic phenomenon accompanied by the continuous production of new types of matter with distinctive chemical properties. This work was predominantly chemical in character and led to

Rutherford receiving in 1908 the Nobel Prize in chemistry.

In 1907, Rutherford left Montreal for Manchester. By this time the general nature of radioactivity had been made clear, the disintegration theory was established, and the series of changes in uranium, thorium and actinium were understood. The happiest part of Rutherford's life was spent in Manchester, where he gathered around him a team of able and enthusiastic workers, and it was while there that the most dramatic event of his scientific career happened, namely, the discovery of the real nature of the atom. His work in Manchester was interrupted by the Great War, but at the end of 1918 he returned with renewed vigour to attack the structure of the nucleus, and within a year his efforts were rewarded, for he proved that nitrogen was destroyed by alpha particles and that hydrogen was a product. From that day to this there has been a continuous and almost bewildering addition to our knowledge of the structure of the nucleus.

Sir Henry Tizard said that Rutherford's influence on chemistry can be summarized in the following way. By his early work on the disintegration of

elements he destroyed the chemist's conception of the nature of atoms, and by doing so gave the atomic conception of matter a reality which it never had before. By his work on the scattering of alpha rays he removed the blot on the periodic system by removing its foundation and replacing it with something better. In doing so, he caused the development of a new and fruitful conception of valency. By his work on transmutation of elements he opened up an immense field of experimental work for the chemist, a field which few can doubt will yield results of the utmost importance in biology as well as in chemistry.

The secret of Rutherford's success in inspiring others lay not only in his genius but also in his unselfishness. Surely there was never a great man who gave so much credit to others. It was a pity, said Sir Henry Tizard, that Rutherford had no Boswell; that none of the men who worked in constant contact with him had made notes of his ways, of his sayings, of his few mistakes as well as his many successes; of his manners, good and bad, and of his faults as well as of his virtues. Rutherford's name will live for ever in the history of our times as no man of science has ever lived before.

Electric Propulsion of Ships

IN a paper read to the North-East Coast Institution of Engineers and Shipbuilders at Newcastle-on-Tyne on December 18 by Mr. L. R. Horne, the development of the electric propulsion of ships was traced over the last hundred years.

In 1839, Yacobi made the first successful experiment. He built a boat capable of carrying twelve passengers and propelled it by an electric motor connected with a battery of 69 Grove cells. A speed of between two and three miles an hour was obtained. Owing to the imperfections in the motor, the idea did not receive any wide practical application and the experiment was soon forgotten. In 1882, an iron boat was electrically propelled on the Thames. In 1886, the *Naudius* was built at Tilbury and fitted with twin screws driven by electric motors. In 1888, a submarine, the *Gymnote*, 59 ft. long and displacing 30 tons, was fitted with a 50-h.p. motor and attained a speed of eight miles per hour (7 knots). The vessel was accepted by the French Navy. In the United States, in 1901, John P. Holland's submarine *Holland VIII* attracted attention and became the model on which Vickers submarines for the British Navy were first designed.

The most successful of the experiments in the early years of the century was made in Russia, and the machinery was constructed in Sweden by the firms now called the Atlas Diesel Co. and the A.S.E.A. This vessel was the *M.S. Vandal*, an 1100-ton shallow-draught tanker, built for service on the Volga and the Caspian Sea in 1903. The machinery consisted of three three-cylinder four-stroke cycle, single-acting engines, placed amidship, and each driving a dynamo and exciter, at 240 r.p.m. The propeller speeds could be varied from 20 to 300 r.p.m. with voltages up to 500. Reversal took 8-12 seconds. The weight of the engines, which were each rated at 120 h.p., was 48 tons, and that of the electrical equipment was 31 tons. The vessel continued in service for ten years, and similar installations followed.

So far, the development of electric propulsion was invariably associated with direct current machinery. During 1910-1911, Mr. Henry Mavor evolved from his experiments the passenger launch *Electric Arc*. This was probably the first experiment with alternating current for propulsion. A petrol engine of 45 h.p. was designed to run at 700 r.p.m. and was directly coupled to an alternator, which carried windings which gave four and six pole fields. Speeds of 7½ and 5 knots were obtained.

While European engineers may fairly claim that the initial stages of the development of the electric

drive were the results of their inspiration and work, the most important landmark in its history was the decision of the U.S. Navy Department, shortly before the Great War, to utilize electric drive in its capital ships. Once it was convinced that the scheme was possible, the method was carried out boldly. Electric drive had been found practical with a.c. machinery up to 50 h.p., but at 600 h.p. it was not so good. Tests were made forthwith on a 7,000 h.p. collier and then on the electric propulsion of a battleship. The experimental installation was put in a twin-screw collier *Jupiter* (now an aircraft carrier called *Langley*), completed in 1913, and found most satisfactory. The battleship *New Mexico*, then under construction as a geared-turbine vessel, was consequently fitted with electric drive. A number of U.S. battleships and their two most powerful aircraft carriers have been provided with electric propelling machinery.

In Great Britain, in 1920, there was no enthusiasm for electric drive in any of its forms, but on this date one of the most conservative shipping companies ordered the *Viceroy of India*, and this ship with turbo-electric drive and synchronous motors was a brilliant success. Service speeds of 18½ and 16 knots were given.

The climax of the development of electric drive, at least in the mercantile marine, came in 1935 with the commissioning of the *Normandie*. The machinery installation of this ship was designed for continuous operation at 160,000 h.p., and this power must have been exceeded when it steamed across the Atlantic at 31 knots.

In spite, however, of recent developments, the proportion of large new vessels installed with turbo-electric drive is small. In the latest returns, record is made of forty-one vessels of 469,000 tons so propelled out of a total of 1,264 vessels of 9,439,000 tons driven by turbines. The explanation would appear to be that, in general, owners prefer the type of machinery which they and their engineering staffs understand best.

In the field of small vessels, the rivalry between the different types of engines and systems of distribution is more intense and the successful progress of electric drive is more definite. A large proportion of vessels fitted with Diesel-electric drive are used in inland waters or are of less than 100 tons gross, or for some other reason are not included in classification returns. Probably there are about 250 vessels using Diesel-electric systems, and their total horse-power is of the order of 250,000. The established success of electric tugs promises an increase in the number of small vessels so driven.

Societies and Academies

Italian Association for the Advancement of Science

In the spring of 1839 many distinguished individuals in Great Britain received circulars announcing the formation of an Italian Association for the Advancement of Science and inviting co-operation in its work. The circular contained the signatures, among others, of Prince Carlo L. Buonaparte, Chev. Antinori, director of the Royal Museum of Natural History in Florence, G. B. Amici, the astronomer and chancellor of the University of Pisa and of Prof. Savi, professor of natural history there. A translation of a part of the circular was given in the *Athenaeum* of April 20, 1839. "Following the advice of many, and the approbation of others," the circular said, "and in conformity with the successful practice in Germany, we have now to announce that from the 1st to the 15th of October will be opened the Association of the Professors and Cultivators of the Physical Sciences in Italy, including Medicine and Agriculture."

The Medical Society of Bombay

On April 20, 1839, the *Athenaeum* published a notice of the "Transactions of the Medical and Physical Society of Bombay, Vol. 1". "From the present volume," the journal said, "we learn that a new society has been formed for the purpose of medical improvement in the East; and it is remarkable on two accounts: First, we observe in it a tendency to return to the methods of the older physicians, and to look to external natural agents, as indexes pointing to the character of diseases. . . . The second circumstance to which we have alluded, is a desire manifested by the profession 'to give the permanent benefits of medical science to the people of India, by introducing an efficient system of medical education'. This is a matter of more extended importance than regards its simple relation to the health of the Hindoo population."
